Abstract

Let $G = (V(G), E(G))$ be a nontrivial connected graph of order n with an edge-coloring $c : E(G) \rightarrow \{1, 2, \dots, q\}$, $q \in \mathbb{N}$, where adjacent edges may be colored the same. A tree T in G is a *rainbow tree* if no two edges of T receive the same color. For a vertex set $S \subseteq V(G)$, a tree connecting S in G is called an S -tree. The minimum number of colors that are needed in an edge-coloring of G such that there is a rainbow S -tree for each k -subset S of $V(G)$ is called the k -rainbow index of G , denoted by $rx_k(G)$, where k is an integer such that $2 \leq k \leq n$. Chartrand *et al.* got that the k -rainbow index of a tree is $n - 1$ and the k -rainbow index of a unicyclic graph is $n - 1$ or $n - 2$. So there is an intriguing problem: Characterize graphs with the k -rainbow index $n - 1$ and $n - 2$. In this paper, we focus on $k = 3$, and characterize the graphs whose 3-rainbow index is $n - 1$ and $n - 2$, respectively.

Keywords: rainbow S -tree, k -rainbow index.
