#### Abstract

A simplex of a graph $G$ is a subgraph of $G$ which is a complete graph. The simplex graph $\operatorname{Simp}(G)$ of $G$ is the graph whose vertex set is the set of all simplices of $G$ and in which two vertices are adjacent if and only if they have a non-empty intersection. The simplex graph operator is the operator which to every graph $G$ assigns its simplex graph $\operatorname{Simp}(G)$. The paper studies graphs which are fixed in this operator and gives a partial answer to a problem suggested by E. Prisner.

Keywords: simplex of a graph, simplex operator, limit cardinal number.
1991 Mathematics Subject Classification: 05C75.

In [1], page 131, E. Prisner posed the problem whether there are infinite Simp-periodic graphs other than those consisting of isolated vertices. This paper is a contribution to that problem. We consider undirected graphs without loops and multiple edges.

A simplex in a graph $G$ is a subgraph of $G$ which is a complete graph. (It need not be maximal, hence this concept is broader than that of a clique). If a simplex has $k$ vertices, it is called a $k$-simplex. Also a 1 -simplex is considered; it consists of one vertex. The simplex $\operatorname{graph} \operatorname{Simp}(G)$ of $G$ is the graph whose vertex set is the set of all simplices of $G$ and in which two vertices are adjacent if and only if they have a non-empty intersection (as simplices). The simplex graph operator is the operator which assigns to every graph $G$ its simplex graph $\operatorname{Simp}(G)$. A graph $G$ is said to be Simpfixed, if it is a fixpoint of the simplex graph operator, i.e. if $\operatorname{Simp}(G) \cong G$.

The graph $G$ is said to be Simp-periodic, if it is a fixpoint of some iteration of the simplex graph operator.

The mentioned problem from [1] concerns Simp-periodic graphs, but we shall treat only Simp-fixed graphs. Obviously every graph consisting of isolated vertices (regular graph of degree 0 ) is Simp-fixed and also the empty graph (in which both the vertex set and the edge set are empty) is Simp-fixed. No other finite graph is Simp-fixed. Namely, the set of simplices of $G$ includes all 1 -simplices and their number is equal to the number of vertices of $G$. If $G$ has at least one edge, it has, moreover, $k$-simplices for $k \geq 2$ and thus the vertex set of $\operatorname{Simp}(G)$ has more elements than the vertex set of $G$ and $\operatorname{Simp}(G)$ cannot be isomorphic to $G$. Therefore there is a question whether an infinite graph exists which is Simp-fixed and has at least one edge.

The first theorem will have a preparatory character.
Theorem 1. Let $G$ be a Simp-fixed graph. Then no vertex of $G$ has a finite degree greater than one.

Proof. Suppose the contrary. Let $r$ be the least integer greater than one such that $G$ contains a vertex of degree $r$. Let a vertex $v_{0}$ have the degree $r$. By $v_{1}, \ldots, v_{r}$ we denote the vertices adjacent to $v_{0}$. As $G$ is Simp-fixed, there exist simplices $S_{0}, S_{1}, \ldots, S_{r}$ in $G$ to which the vertices $v_{0}, v_{1}, \ldots, v_{r}$ correspond; the simplex $S_{0}$ has non-empty intersections with all the simplices $S_{1}, \ldots, S_{r}$. Suppose that $S_{0}$ is a $k$-simplex for $k \geq 2$. Then it contains two distinct vertices $w_{1}, w_{2}$. If both $w_{1}, w_{2}$ have degree 1 , then $S_{0}$ is a 2 -simplex forming a connected component of $G$. Then $G$ must contain a connected component whose image in the operator Simp is $S_{0}$; but a 2 -simplex is not a simplex graph for any graph. Therefore at least one of the vertices $w_{1}, w_{2}$, say $w_{1}$, has degree greater than one. As $r$ is the minimum of such degrees, the degree of $w_{1}$ is at least $r$. The vertex $w_{1}$ is incident to at least $r-1$ edges distinct from $w_{1} w_{2}$; these edges with their end vertices form 2 -simplices having a non-empty intersection with $S_{0}$. Further such simplices are 1-simplices consisting of $w_{1}$ and consisting of $w_{2}$. There are at least $r+1$ simplices having non-empty intersections with $S_{0}$ and thus the degree of $v_{0}$ is at least $r+1$, which is a contradiction. We have proved that $S_{0}$ is a 1 -simplex; let it consist of a vertex $S_{0}$. The vertex $S_{0}$ cannot have degree 0 or 1 , because so would have also $v_{0}$. Therefore the degree of $S_{0}$ is at least $r$. Each edge incident with $S_{0}$ forms a 2 - simplex. As the degree of $v_{0}$ is $r$, no $k$-simplices for $k \geq 3$ containing $S_{0}$ exist; the neighbours of $S_{0}$ form an independent set and their number, i.e. the degree of $S_{0}$, is exactly $r$. Any two of the
mentioned 2-simplices have a common vertex $S_{0}$ and thus the neighbours of $v_{0}$ form an $r$-simplex. We have proved that a vertex of $G$ with degree $r$ has the property that its neighbours form an $r$-simplex. But then this must hold for $S_{0}$, too, which is a contradiction. This proves the assertion.

At considerations concerning infinite cardinal numbers we shall suppose the validity of Axiom of Choice and the existence of well-ordering of cardinal numbers which follows from it. As usual, by $\aleph_{0}$ we denote the cardinality of the set of positive integers, by $\aleph_{\alpha+1}$ for a positive integer $\alpha$ we denote the cardinal number immediately following after $\aleph_{\alpha}$. By $\aleph_{\omega}$ we denote the least cardinal number which is greater then $\aleph_{\alpha}$ for every non-negative integer $\alpha$. It is well-known $\aleph_{\omega}=\sum_{\alpha<\omega} \aleph_{\alpha}$.

Theorem 2. Any graph $G$ which contains at least one edge and whose vertex set has cardinality less that $\aleph_{\omega}$ is not Simp-fixed.
Proof. Suppose that there exists a Simp-fixed graph $G$ having at least one edge. Then $G$ contains vertices of non-zero degrees. If the maximum degree of a vertex of $G$ is 1 , then $G$ contains at least one connected component which is a 2 -simplex. The existence of such connected component was excluded in the proof of Theorem 1. Therefore $G$ contains at least one vertex of degree grather than 1 . According to Theorem 1 such a degree cannot be finite. Thus $G$ contains a vertex $v_{0}$ of infinite degree $r$. If $r \geq \aleph_{\omega}$, then also $|V(G)| \geq \aleph_{\omega}$ and the assertion is true. Thus suppose $r=\aleph_{\alpha}$ for some non-negative integer $\alpha$. The edges incident with $v_{0}$ together with their end vertices form 2 -simplices. Any two of these 2 -simplices have a common vertex $v_{0}$ and, as $G$ is Simp-fixed, vertices of an $\aleph_{\alpha}$-simplex $S_{1}$ in $G$ correspond to them. Choose a vertex $v_{1}$ in $S_{1}$ and consider all simplices which are subgraphs of $S$ and contain $v_{1}$. Their number is $\exp \aleph_{\alpha}$ and any two of them have a common vertex $v_{1}$; therefore vertices of an $\left(\exp \aleph_{\alpha}\right)$-simplex $S_{2}$ in $G$ correspond to them. We can proceed further, constructing always $S_{n+1}$ from $S_{n}$. We have $\left|V\left(S_{2}\right)\right|=\exp \aleph_{\alpha} \geq \aleph_{\alpha+1},\left|V\left(S_{3}\right)\right|=\exp \aleph_{\alpha} \geq \exp \aleph_{\alpha+1} \geq \aleph_{\alpha+2}$ etc., in general $\left|V\left(S_{n}\right)\right| \geq \aleph_{\alpha+n+1}$. Therefore the vertex set of $G$ contains subsets of all cardinalities which are less that $\aleph_{\omega}$ and hence its cardinality is at least $\aleph_{\omega}$.
A further theorem concerns a more general question.
Theorem 3. Let $G$ be a connected graph such that the cardinalities of $V(G)$ and of $V(\operatorname{Simp}(\operatorname{Simp}(G)))$ are equal. Then the cardinality of $V(G)$ is 0,1 or a limit cardinal number.

Proof. At the beginning of this paper we have written that for a finite graph $G$ having at least one edge always $|V(\operatorname{Simp}(G))|>|V(G)|$. Thus suppose that $|V(G)|$ is equal to some isolated infinite cardinal number $\aleph_{\beta+1}$, where $\beta$ is an ordinal number. If $G$ contains a vertex of degree $\aleph_{\beta+1}$, then $\operatorname{Simp}(G)$ contains an $\aleph_{\beta+1}$-simplex and $\operatorname{Simp}(\operatorname{Simp}(G))$ contains an $\left(\exp \aleph_{\beta+1}\right)$-simplex and thus $|V(\operatorname{Simp}(\operatorname{Simp}(G)))| \geq \exp \aleph_{\beta+1}>\aleph_{\beta+1}$. Hence all vertices of $G$ must have degrees less than $\aleph_{\beta+1}$, i.e. less than or equal to $\aleph_{\beta}$. Choose a vertex $v$ of $G$ and for each non-negative integer $k$ by $N_{k}(v)$ denote the set of all vertices whose distance from $v$ in $G$ is equal to $k$. As $G$ is connected, the union of $N_{k}(v)$ for all non-negative integers $k$ is $V(G)$. By induction we prove that $\left|N_{k}(v)\right| \leq \aleph_{\beta}$ for each $k$. For $k=0$ we have $N_{0}(v)=\{v\}$ and $\left|N_{0}(v)\right|=1<\aleph_{\beta}$. Now suppose that the assertion is true for some $k$. Each vertex of $N_{k+1}(v)$ is adjacent to a vertex of $N_{k}(v)$ and the cardinality of $N_{k+1}(v)$ cannot exceed the cardinality of the set of edges joining vertices of $N_{k}(v)$ with vertices of $N_{k+1}(v)$. As $\left|N_{k}(v)\right| \leq \aleph_{\beta}$ and each vertex of $N_{k}(v)$ has degree at most $\aleph_{\beta}$, there are at most $\aleph_{\beta}$ such edges and $\left|N_{k+1}(v)\right| \leq \aleph_{\beta}$. And then $V(G)$ is the union of $\aleph_{0}$ disjoint sets of cardinalities at most $\aleph_{\beta}$, hence also $|V(G)| \leq \aleph_{\beta}<\aleph_{\beta+1}$, which is a contradiction. This proves the assertion.

Note that in this case also the limit cardinal number $\aleph_{0}$ may occur. This theorem has importance for Simp-periodic graphs. By Simp ${ }^{k}$ we denote the $k$-th iteration of Simp, where $k$ is a positive integer. From the inequality $|V(G)| \leq|V(\operatorname{Simp}(G))|$ it is clear that if $\operatorname{Simp}^{k}(G) \cong G$, then $|V(G)|=$ $|V(\operatorname{Simp}(\operatorname{Simp}(G)))|$, the number $k$ being an arbitrary positive integer, and the following corollary holds.

Corollary. Let $G$ be a connected Simp-periodic graph. Then the cardinality of $V(G)$ is 0,1 or a limit cardinal number.

The last theorem will concern locally finite graphs. Remember the wellknown fact that a connected infinite locally finite graph has always a countable vertex set.

Theorem 4. Let $G$ be an infinite locally finite graph. Then so is $\operatorname{Simp}(G)$.
Proof. Let $S$ be a simplex in $G$; as $G$ is locally finite, $S$ is finite. Each vertex $v$ of $S$ can be contained only in a finite number of simplices of $G$, because this number cannot exceed the number of all subsets of the set of neighbours of $v$. As also $S$ is finite, the set of all simplices having non-empty intersections with $S$ is finite: the vertex of $\operatorname{Simp}(G)$ coressponding to $S$ has
a finite degree. As $S$ was chosen arbitrarily, the $\operatorname{graph} \operatorname{Simp}(G)$ is locally finite.
