# ON DISTANCE EDGE COLOURINGS OF A CYCLIC MULTIGRAPH 

Zdziseaw Skupień<br>Faculty of Applied Mathematics<br>University of Mining and Metallurgy AGH<br>al. Mickiewicza 30, 30-059 Kraków, Poland<br>e-mail: skupien@uci.agh.edu.pl

We shall use the distance chromatic index defined by the present author in early nineties, cf. [5] or [4] of 1993. The edge distance of two edges in a multigraph $M$ is defined to be their distance in the line graph $L(M)$ of $M$. Given a positive integer $d$, define the $d^{+}$-chromatic index of the multigraph $M$, denoted by $q^{(d)}(M)$, to be equal to the chromatic number $\chi$ of the $d$ th power of the line graph $L(M)$,

$$
q^{(d)}(M)=\chi\left(L(M)^{d}\right) .
$$

Then the colour classes are matchings in $M$ with edges at edge distance larger than $d$ apart.

Call $C$ to be a cyclic multigraph if $C$ consists of a cycle on $n$ vertices with possibly more than one edge between two consecutive vertices.

The following problem was presented in [6].
Problem. Given an integer $d \geq 2$ and a cyclic multigraph $C$, find (or estimate) $q^{(d)}(C)$, the $d^{+}$-chromatic index of $C$.

In other words, generalize the following formula due to Berge [1] for the ordinary chromatic index $\left(q=q^{1}\right)$

$$
q(C)= \begin{cases}\max \left\{\Delta(C),\left\lceil\frac{e(C)}{\left\lfloor\frac{n}{2}\right\rfloor}\right\rceil\right\} & \text { for odd } n, \\ \Delta(C) & \text { for even } n,\end{cases}
$$

where $\Delta(C)$ and $e(C)$ are the maximum degree among vertices and the size of $C$, respectively.

Remarks 1. $2^{+}$-chromatic index $q^{(2)}$ is known under the name strong chromatic index, estimations of $q^{(2)}(C)$ being studied in $[2,3]$.
2. In [5] it is proved that

$$
q^{(d)}\left({ }^{p} C_{n}\right)=\left\{\begin{array}{cl}
p n & \text { if } n \leq 2 d+1 \\
{\left[\frac{p n}{\left\lfloor\frac{n}{d+1}\right\rfloor}\right\rceil} & \text { if } n \geq d+1
\end{array}\right.
$$

where ${ }^{p} C_{n}$ is the cyclic multigraph $C$ with all edge multiplicities equal to $p$.
3. Let $M$ be a loopless multigraph whose underlying graph is a forest. Then $q^{(d)}(M)$, the $d^{+}$-chromatic index of $M$, can be seen to be equal to the diameter- $d$ cluster (or diameter- $d$ edge-clique) number of $M$ (i.e., the density of the $d$ th power, $L(M)^{d}$, of the line graph of $\left.M\right)$. This extends the known corresponding results on a tree [5] and on $q^{(2)}(M)$ in [2].
