# A NOTE ON DOMINATION PARAMETERS OF THE CONJUNCTION OF TWO SPECIAL GRAPHS 

Maciej Zwierzchowski<br>Institute of Mathematics<br>University of Technology of Szczecin<br>al. Piastów 48/49, 70-310 Szczecin, Poland<br>e-mail: mzwierz@arcadia.tuniv.szczecin.pl

#### Abstract

A dominating set $D$ of $G$ is called a split dominating set of $G$ if the subgraph induced by the subset $V(G)-D$ is disconnected. The cardinality of a minimum split dominating set is called the minimum split domination number of $G$. Such subset and such number was introduced in [4]. In [2], [3] the authors estimated the domination number of products of graphs. More precisely, they were study products of paths. Inspired by those results we give another estimation of the domination number of the conjunction (the cross product) $P_{n} \wedge G$. The split domination number of $P_{n} \wedge G$ also is determined. To estimate this number we use the minimum connected domination number $\gamma_{c}(G)$.

Keywords: domination parameters, conjunction of graphs.
2000 Mathematics Subject Classification: 05C69.

## 1. Definitions and Notations

In this paper we discuss finite connected, undirected simple graphs. For any graph $G$ we denote $V(G)$ and $E(G)$, the vertex set of $G$ and the edge set of $G$, respectively. We say that $G$ is of order $n$ if $n$ is a cardinality of $V(G)$. By $\langle X\rangle_{G}$ we denote a subgraph of $G$ which is induced by a subset $X \subset V(G)$. A hanging vertex is a vertex of $G$ adjacent to exactly one vertex in $G$. The complement of $G$ is denoted by $\bar{G}$. A subset $D \subseteq V(G)$ is a dominating set
of $G$ if for every $x \in V(G)-D$ there is a vertex $y \in D$ such that $x y \in E(G)$. We will also write that $x$ is dominated by $D$ or by $y$ in $G$.

In [4] it was introduced the notion of split dominating set of a graph. We say that a dominating set $D \subseteq V(G)$ is a split dominating set of $G$ if the induced subgraph $\langle V(G)-D\rangle_{G}$ is disconnected. A dominating set $D \subseteq V(G)$ is a connected dominating set of $G$, (see [5]) if the induced subgraph $\langle D\rangle_{G}$ is connected. The domination number [the split domination number, the connected domination number] of a graph $G$, denoted by $\gamma(G)$, $\left[\gamma_{s}(G), \gamma_{c}(G)\right]$ is the cardinality of a minimum dominating [a minimum split dominating, a minimum connected dominating] set of $G$. It is easy to see that $\gamma(G) \leq \gamma_{s}(G)$ and also $\gamma(G) \leq \gamma_{c}(G)$. A dominating set $D$ is called a $\gamma(G)$ set $\left[\gamma_{s}(G)\right.$-set, $\gamma_{c}(G)$-set] if $D$ realizes the domination [split domination, connected domination] number, respectively. Note that there exists a $\gamma_{c}(G)$ set if and only if $G$ is connected. The conjunction of two graphs $G$ and $H$ is a graph $G \wedge H$, with $V(G \wedge H)=V(G) \times V(H)$ and $\left(g_{1}, h_{1}\right)\left(g_{2}, h_{2}\right) \in E(G \wedge H)$ if and only if $g_{1} g_{2} \in E(G)$ and $h_{1} h_{2} \in E(H)$. By $P_{n}$ we denote an induced path on $n \geq 2$ vertices meant as a graph with $V\left(P_{n}\right)=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$ and $E\left(P_{n}\right)=\left\{x_{i} x_{i+1}: i=1,2, \ldots, n-1\right\}$. If $V(G)=\left\{y_{1}, y_{2}, \ldots, y_{m}\right\}$, then the copy $G^{*}$ of $G$ is the graph with the vertex set $V\left(G^{*}\right)=\left\{y_{1}^{*}, y_{2}^{*}, \ldots, y_{n}^{*}\right\}$ and $y_{i}^{*} y_{j}^{*} \in E\left(G^{*}\right)$ if and only if $y_{i} y_{j} \in E(G)$, where $y_{i}^{*}$ corresponds to $y_{i}$. Further, let $D=\left\{y_{1}, y_{2}, \ldots, y_{r}\right\} \subset V(G)$, then the subset $D^{*}=\left\{y_{1}^{*}, y_{2}^{*}, \ldots, y_{m}^{*}\right\} \subset$ $V\left(G^{*}\right)$ is called a duplication of $D$ into the vertex set $V\left(G^{*}\right)$ of the copy $G^{*}$ or shorter into $G^{*}$.

We consider the conjunction $P_{n} \wedge G$, for $n \geq 2$ with a special graph $G$. Before proceeding we introduce some notation with respect to $P_{n} \wedge G$. If $y_{j} \in V(G)$, then the vertex $\left(x_{i}, y_{j}\right)$ of the conjunction of $P_{n} \wedge G$ is simply written as $x_{j}^{i}$. For a fixed integer $i$ we put $X_{i}=\left\{x_{j}^{i}: 1 \leq j \leq|V(G)|\right\}$. A set $B$ of all vertices belonging to $k$ consecutive sets $X_{i+1}, \ldots, X_{i+k}$ is called a block of a graph $P_{n} \wedge G$ of size $k \times|V(G)|$. For a convenience, the set $X_{i}$ we will call the $i$-th column of a graph $P_{n} \wedge G$. Any other terms not defined in this paper can be found in [1].

## 2. Introduction

In this section we introduce some basic facts which will be useful in further investigations. It was proved in [4], that

Theorem 1 [4]. $\gamma_{s}\left(P_{n}\right)=\left\lceil\frac{n}{3}\right\rceil$, for $n \geq 3$.

Theorem 2 [4]. For any noncomplete graph $G$ with at least one hanging vertex

$$
\gamma_{s}(G)=\gamma(G) .
$$

Next, it is easy to check that
Proposition 3. There is no a split dominating set of $\overline{P_{n}}$, for $i=1,2,3$.
Proposition 4. $\gamma_{s}\left(\overline{P_{4}}\right)=2$, since $\overline{P_{4}} \cong P_{4}$.
Now, we calculate a split domination number of $\overline{P_{n}}$ if $n \geq 5$.
Theorem 5. $\gamma_{s}\left(\overline{P_{n}}\right)=n-3$, for $n \geq 5$.
Proof. Let $V\left(P_{n}\right)=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$, such that $d_{P_{n}}\left(x_{1}\right)=d_{P_{n}}\left(x_{n}\right)=1$ and $d_{P_{n}}\left(x_{i}\right)=2$, for $i=2,3, \ldots, n-1$. At the beginning we can observe that $d_{\overline{P_{n}}}\left(x_{1}\right)=d_{\overline{P_{n}}}\left(x_{n}\right)=n-2$ and $d_{\overline{P_{n}}}\left(x_{i}\right)=n-3$, for $i=2,3, \ldots, n-1$. Now, we show that the induced subgraph $H=\left\langle\left\{x_{n_{1}}, x_{n_{2}}, \ldots, x_{n_{k}}\right\}\right\rangle_{\overline{P_{n}}}$ is connected, when $n_{1}<n_{2}<\ldots<n_{k}$, for $k \geq 4$. Since $n_{3}-n_{1} \geq 2, n_{4}-n_{1} \geq$ $2, \ldots, n_{k}-n_{1} \geq 2$, then $x_{n_{1}}$ is adjacent to $x_{n_{s}}$ in $\overline{P_{n}}$, for $s=3,4, \ldots, k$. Hence $H_{1}=\left\langle\left\{x_{n_{1}}, x_{n_{3}}, x_{n_{4}}, \ldots, x_{n_{k}}\right\}\right\rangle_{\overline{P_{n}}}$ is a connected subgraph. Arguing as above we prove that $H_{2}=\left\langle\left\{x_{n_{2}}, x_{n_{4}}, x_{n_{5}}, \ldots, x_{n_{k}}\right\}\right\rangle_{\overline{P_{n}}}$ also is connected. Since $k \geq 4$, then $V\left(H_{1}\right) \cap V\left(H_{2}\right) \neq \emptyset$ and $H=\left\langle V\left(H_{1}\right) \cup V\left(H_{2}\right)\right\rangle_{\overline{P_{n}}}$ is connected. This means that there is no a disconnected subgraph of $\overline{P_{n}}$ of order at least $n-4$. To complete the proof we construct a split dominating set $D$ of $\overline{P_{n}}$, such that $|D|=n-3$. Let $D$ consists of vertices $x_{i}$, for $i=4,5, \ldots, n$. Since $n \geq 5$, thus $D \neq \emptyset$ and $V\left(\overline{P_{n}}\right)-D=\left\{x_{1}, x_{2}, x_{3}\right\}$. Moreover, vertices $x_{1}, x_{2}$ are adjacent to $x_{4} \in D$ in $\overline{P_{n}}$ and $x_{3}$ is adjacent to $x_{5} \in D$ in $\overline{P_{n}}$. Furthermore, $x_{2}$ is an isolated vertex in $\left\langle V\left(\overline{P_{n}}\right)-D\right\rangle_{\overline{P_{n}}}$. All this together gives that $D$ is the minimum split dominating set of $\overline{P_{n}}$ of order $n-3$, as required.
From the structure of $P_{n}, \overline{P_{n}}$ and from the definition of the connected domination number it follows immediately

## Proposition 6.

$$
\begin{array}{ll}
\gamma_{c}\left(P_{n}\right)=n-2, & \text { for } n \geq 3 \text { and } \\
\gamma_{c}\left(\overline{P_{n}}\right)=2, & \text { for } n \geq 4
\end{array}
$$

From Theorem 1, Theorem 5 and Proposition 6 it follows the NordhausGaddum type result

## Theorem 7.

$$
\begin{array}{ll}
\gamma_{s}\left(P_{n}\right)+\gamma_{s}\left(\overline{P_{n}}\right)=\left\lceil\frac{n}{3}\right\rceil+n-3, & \text { for } n \geq 5 \\
\gamma_{c}\left(P_{n}\right)+\gamma_{c}\left(\overline{P_{n}}\right)=n, & \text { for } n \geq 4
\end{array}
$$

## 3. Main Results

Proposition 8. For any graph $G, \gamma\left(P_{2} \wedge G\right) \leq 2 \gamma(G)$.
Proof. Let $D=\left\{x_{1}, x_{2}, \ldots, x_{s}\right\}$ be a minimum dominating set of $G$. Duplicating $D$ into two columns $P_{2} \wedge G$ we obtain a subset $A_{2}=\left\{x_{1}^{1}, x_{2}^{1}, \ldots, x_{s}^{1}\right.$, $\left.x_{1}^{2}, x_{2}^{2}, \ldots, x_{s}^{2}\right\} \subset V\left(P_{2} \wedge G\right)$. We show that $A_{2}$ is a dominating set of $P_{2} \wedge G$. Let $x_{j}^{1} \in\left(V\left(P_{2} \wedge G\right)-A_{2}\right)$. Since $D$ is a dominating set of $G$, then there exists a vertex $x_{k}$ of $D$ in $G$, such that $x_{k} x_{j} \in E(G)$. Further, by the definition of $P_{2} \wedge G$ and by a construction of the subset $A_{2}$ we have that $x_{j}^{1} x_{k}^{2} \in E\left(P_{2} \wedge G\right)$ and $x_{k}^{2} \in A_{2}$, respectively. Hence $x_{j}^{1}$ is dominated by $A_{2}$ in $P_{2} \wedge G$. Similarly, we can show that the vertex $x_{j}^{2} \in\left(V\left(P_{2} \wedge G\right)-A_{2}\right)$ is dominated by $A_{2}$ in $P_{2} \wedge G$. All this together gives that $A_{2}$ is a dominating set of $P_{2} \wedge G$ and $\gamma\left(P_{2} \wedge G\right) \leq\left|A_{2}\right|=2 \gamma(G)$, as required.
It follows immediately from the obvious inequality $\gamma(G) \leq \gamma_{c}(G)$ and from the above proposition that

Corollary 9. For any connected graph $G, \gamma\left(P_{2} \wedge G\right) \leq 2 \gamma_{c}(G)$.
Proposition 10. For any graph $G$ with $\gamma_{c}(G) \geq 2$,

$$
\gamma\left(P_{3} \wedge G\right) \leq 2 \gamma_{c}(G)
$$

Proof. Let $D$ be a $\gamma_{c}(G)$-set. Put $A_{3}=\left\{x_{j}^{2}, x_{j}^{3}\right.$ : for all $\left.x_{j} \in D\right\}$. Now we show that $A_{3}$ is a dominating set of $P_{3} \wedge G$. Arguing as in a proof of Proposition 8 , we see that $A_{3}$ dominates vertices $x_{j}^{2}, x_{j}^{3} \in\left(V\left(P_{3} \wedge G\right)-A_{3}\right)$ in $P_{3} \wedge G$. To complete the proof we must show that any vertex from $X_{1}$ is dominated by $A_{3}$ in $P_{3} \wedge G$. We recall that $X_{1}$ is the first column of the graph $P_{3} \wedge G$ as it was mentioned earlier. Let $x_{j}^{1} \in X_{1}$. If $x_{j} \in V(G)-D$, then it
is dominated by a vertex $x_{k} \in D$ and in a consequence $x_{j}^{1}$ is dominated by $x_{k}^{2} \in A_{3}$. Assume that $x_{j} \in D$. Since $\langle D\rangle_{G}$ is connected and $|D|=\gamma_{c}(G) \geq 2$, thus there exists a vertex $x_{k} \in D$ different from $x_{j}$, such that $x_{j} x_{k} \in E(G)$. Moreover, $x_{j}^{1} x_{k}^{2} \in E\left(P_{3} \wedge G\right)$. This means that $x_{j}^{1}$ is dominated by $A_{3}$ in $P_{3} \wedge G$ because of $x_{k}^{2} \in A_{3}$. Hence $A_{3}$ is a dominating set of $P_{3} \wedge G$. Since $\gamma\left(P_{3} \wedge G\right) \leq\left|A_{3}\right|=2 \gamma_{c}(G)$, thus the theorem is true.

Remark 1. It is easy to see that $A_{3}$ also is a dominating set of $P_{4} \wedge G$, where $G$ is a graph with $\gamma_{c}(G) \geq 2$. Hence $\gamma\left(P_{4} \wedge G\right) \leq 2 \gamma_{c}(G)$ with $\gamma_{c}(G) \geq 2$.

Proposition 11. For any graph $G$ with $\gamma_{c}(G) \geq 2$

$$
\gamma\left(P_{5} \wedge G\right) \leq 3 \gamma_{c}(G)
$$

Proof. Let $D=\left\{x_{1}, \ldots, x_{m}\right\}$ be a minimum connected dominating set of $G$. Duplicating $D$ into 2-nd, 3 -rd, 4 -th column of $P_{5} \wedge G$ we obtain a subset

$$
A_{5}=\left\{x_{j}^{i}: i=2,3,4 \text { and } j=1,2, \ldots m\right\} \subset V\left(P_{5} \wedge G\right) .
$$

Simple observation shows that $A_{5}$ is a dominating set of $P_{5} \wedge G$. Thus $\gamma\left(P_{5} \wedge\right.$ $G) \leq\left|A_{5}\right|=3 \gamma_{c}(G)$ and proof is complete.
In [2] it was presented the following result
Proposition 12 [2]. For $n>1$ and every graph $G$ we have

$$
\gamma\left(P_{n} \wedge G\right) \leq 2 \gamma(G)\left(\left\lfloor\frac{n}{4}\right\rfloor+1\right)
$$

Counterexample. Let $P_{n}=P_{3}$ and $G=P_{5}$, then $P_{n} \wedge G=P_{3} \wedge P_{5}$ has two connected components, say $Y_{1}$ and $Y_{2}$. Further, this must be that $\gamma\left(P_{3} \wedge P_{5}\right)=\gamma\left(Y_{1}\right)+\gamma\left(Y_{2}\right)$. It is easy to observe that $\gamma\left(Y_{1}\right)=2$ and $\gamma\left(Y_{2}\right)=3$, thus $\gamma\left(P_{3} \wedge P_{5}\right)=5$. Now, using the estimation from Proposition 12 we obtain $\gamma\left(P_{3} \wedge P_{5}\right) \leq 4\left(\left\lfloor\frac{3}{4}\right\rfloor+1\right)=4$, since $\gamma(G)=\gamma\left(P_{5}\right)=2$. It is not true, since as we noticed $\gamma\left(P_{3} \wedge P_{5}\right)=5$.

Using above facts we give another estimation for $\gamma\left(P_{n} \wedge G\right)$.
Theorem 13. Let $G$ be a graph with $\gamma_{c}(G) \geq 2$. Then, for $n \geq 2$ we have

$$
\gamma\left(P_{n} \wedge G\right) \leq \begin{cases}\gamma_{c}(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+1\right), & \text { if } n \equiv 1(\bmod 4) \\ \gamma_{c}(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+2\right), & \text { otherwise }\end{cases}
$$

Proof. Let $n=4 q+r, q \geq 1,0 \leq r<4, r \neq 1$. Partition the set $V\left(P_{n} \wedge G\right)$ into $q$ blocks $B_{1}, \ldots, B_{q}$ of size $4 \times|V(G)|$ and one block $B_{q+1}$ of size $r \times|V(G)|$ (it can be that $B_{q+1}=\emptyset$ ). Put $A_{j}^{i}$ be a duplication of $A_{j}$ into the block $B_{i}$, for $i=1,2, \ldots, q$ and $j=2,3,5$, where $A_{j}$ is the subset defined in the proofs of above propositions.

If $n=4 q$, then $D=\bigcup_{i=1}^{q} A_{3}^{i}$ is a dominating set of $P_{n} \wedge G$ and

$$
|D|=2 q \gamma_{c}(G)=2\left(\left\lfloor\frac{4 q-1}{4}\right\rfloor+1\right) \gamma_{c}(G)=\gamma_{c}(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+2\right)
$$

If $n=4 q+2$, then $D=\bigcup_{i=1}^{q} A_{3}^{i} \cup A_{2}^{q+1}$ is a dominating set of $P_{n} \wedge G$ and

$$
|D|=2 q \gamma_{c}(G)+2 \gamma_{c}(G)=\left(2\left\lfloor\frac{4 q+1}{4}\right\rfloor+2\right) \gamma_{c}(G)=\gamma_{c}(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+2\right) .
$$

If $n=4 q+3$, then $D=\bigcup_{i=1}^{q+1} A_{3}^{i}$ is a dominating set of $P_{n} \wedge G$ and

$$
|D|=2(q+1) \gamma_{c}(G)=2\left(\left\lfloor\frac{4 q+2}{4}\right\rfloor+1\right) \gamma_{c}(G)=\gamma_{c}(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+2\right) .
$$

Assume that $n=4 q+1$. Thus we create $q-1$ blocks of size $4 \times|V(G)|$, say $B_{1}, \ldots, B_{q-1}$ and one block $B_{q}$ of size $5 \times|V(G)|$. Let $D=\bigcup_{i=1}^{q-1} A_{3}^{i} \cup A_{5}^{q}$, then $D$ is a dominating set of $P_{n} \wedge G$ with

$$
\begin{aligned}
|D| & =2(q-1) \gamma_{c}(G)+3 \gamma_{c}(G)=(2 q+1) \gamma_{c}(G) \\
& =\left(2\left\lfloor\frac{4 q}{4}\right\rfloor+1\right) \gamma_{c}(G)=\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+1\right) \gamma_{c}(G) .
\end{aligned}
$$

Therefore, since $\gamma\left(P_{n} \wedge G\right) \leq|D|$, the result holds, for $n \geq 4$ as it was assumed at the beginning of the proof.

Since $2 \gamma_{c}(G)=\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+2\right) \gamma_{c}(G)$, for $n=2,3,4$ and $3 \gamma_{c}(G)=$ $\left(2\left\lfloor\frac{5-1}{4}\right\rfloor+1\right) \gamma_{c}(G)$, then Theorem 13 was proved for any $n \geq 2$.

Moreover, since $\gamma_{c}\left(\overline{P_{k}}\right)=2$, for $k \geq 4$, then the last result and a simple calculation lead to the following conclusion.

Corollary 14 [2]. For $n \geq 2$ and $k \geq 4$,

$$
\gamma\left(P_{n} \wedge \overline{P_{k}}\right) \leq\left\{\begin{array}{cl}
n, & \text { if } n \equiv 0(\bmod 4), \\
n+1, & \text { if } n \equiv 1(\bmod 4) \\
n+2, & \text { if } n \equiv 2(\bmod 4) .
\end{array}\right.
$$

Mention that for the graph $P_{3} \wedge P_{5}$, considered after Proposition 12, using the estimation from Theorem 13 we have $5=\gamma\left(P_{3} \wedge P_{5}\right) \leq$ $\gamma_{c}\left(P_{5}\right)\left(2\left\lfloor\frac{3-1}{4}\right\rfloor+2\right)=6$.

At the end, we consider the minimum split domination number of the conjunction of $P_{n}$ and a graph $G$ with a special property. First, we assume that $G$ has at least two hanging vertices, then we have

Proposition 15. Let $G$ be a graph with at least one hanging vertex. Then

$$
\gamma_{s}\left(P_{n} \wedge G\right)=\gamma\left(P_{n} \wedge G\right), \text { for } n \geq 2
$$

Proof. Let $G$ be a graph as in the statement of the corollary. Since $G$ has at least one hanging vertex, thus by the definition of $P_{n} \wedge G$, we obtain that $P_{n} \wedge G$ has at least one hanging vertex (note that it has at least two hanging vertices, since $n \geq 2$ ). Then according to Theorem 2 we have that $\gamma_{s}\left(P_{n} \wedge G\right)=\gamma\left(P_{n} \wedge G\right)$, as desired.
Further, we assume that $G$ is a connected graph with the minimum domination number equal to half its order.

The following result was given in [3].
Theorem 16 [3]. A connected graph $G$ of order $2 n \geq 4$ has $\gamma(G)=n$ if and only if either $G \cong C_{4}$ or $G$ satisfies: the vertex set of a graph $G$ can be partitioned into two sets $V_{1}$ and $V_{2}$, such that $\left|V_{1}\right|=\left|V_{2}\right|=n$ with only matching between $V_{1}$ and $V_{2}$ and satisfying $\left\langle V_{1}\right\rangle_{G} \cong \overline{K_{n}}$ and $\left\langle V_{2}\right\rangle_{G}$ is connected.

From the above theorem it follows that the graph $G$ different from $C_{4}$ has at least two hanging vertices. Moreover, according to Proposition 15, we observe that $\gamma_{s}\left(P_{n} \wedge G\right)=\gamma\left(P_{n} \wedge G\right)$, for $G$ mentioned in Theorem 16. Now, we give the estimation for the split domination number with respect to the conjunction of $P_{n}$ and a graph $G$ with the minimum domination number equal to half its order. But first we find a relationship between domination parameters in $G$.

Theorem 17. Let $G$ be a connected graph of order $2 n \geq 4$ with $\gamma(G)=n$. Then $\gamma_{s}(G)=\gamma_{c}(G)=\gamma(G)$.

Proof. Assume that $G \cong C_{4}$. The subset containing exactly two adjacent [not adjacent] vertices realizes $\gamma(G)=2$ and it is a minimum connected [a minimum split dominating] set of $C_{4}$. Thus the result holds, for $C_{4}$. Now, assume that $G$ is different from $C_{4}$. By Theorem 16 we have that $V(G)$ can be partitioned into two sets $V_{1}$ and $V_{2}$ of order $n$, such that $\left\langle V_{2}\right\rangle_{G}$ is connected and $\left\langle V_{1}\right\rangle_{G} \cong \overline{K_{n}}$. This means that the subset $V_{1}$ is a set of all hanging vertices of $G$. Let $D=V_{2}$, since there is a matching between $V_{1}=V(G)-D$ and $D$ in $G$. It means that $D$ is a minimum dominating set of $G$. To complete this theorem, we show that $D$ is a $\gamma_{c}(G)$-set and also a $\gamma_{s}(G)$-set. Because of $\langle D\rangle_{G}$ is connected, as it was stated in Theorem 13 , then $D$ is a $\gamma_{c}(G)$-set. Moreover, since $\langle V(G)-D\rangle_{G} \cong \overline{K_{n}}, n \geq 2$ is disconnected, thus we $D$ is a $\gamma_{s}(G)$-set, proving the theorem.
Finally, using this theorem, Theorem 13 and Proposition 15 we obtain the following estimation for a split dominating number of $P_{n} \wedge G$.

Corollary 18. Let $G$ be a connected graph of order $2 m \geq 4$ with $\gamma(G)=m$. Then

$$
\gamma_{s}\left(P_{n} \wedge G\right)=\gamma\left(P_{n} \wedge G\right) \leq \begin{cases}\gamma(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+1\right), & \text { if } n \equiv 1(\bmod 4), \\ \gamma(G)\left(2\left\lfloor\frac{n-1}{4}\right\rfloor+2\right), & \text { otherwise } .\end{cases}
$$
