# ON THE HETEROCHROMATIC NUMBER OF CIRCULANT DIGRAPHS 

Hortensia Galeana-SÁnchez and Víctor Neumann-Lara<br>Instituto de Matemáticas, UNAM<br>Universidad Nacional Autónoma de México<br>Ciudad Universitaria<br>04510, México, D.F., MÉXICO

#### Abstract

The heterochromatic number $h c(D)$ of a digraph $D$, is the minimum integer $k$ such that for every partition of $V(D)$ into $k$ classes, there is a cyclic triangle whose three vertices belong to different classes.

For any two integers $s$ and $n$ with $1 \leq s \leq n$, let $D_{n, s}$ be the oriented graph such that $V\left(D_{n, s}\right)$ is the set of integers $\bmod 2 n+1$ and $A\left(D_{n, s}\right)=\{(i, j): j-i \in\{1,2, \ldots, n\} \backslash\{s\}\}$.

In this paper we prove that $h c\left(D_{n, s}\right) \leq 5$ for $n \geq 7$. The bound is tight since equality holds when $s \in\left\{n, \frac{2 n+1}{3}\right\}$.

Keywords: circulant tournament, vertex colouring, heterochromatic number, heterochromatic triangle.
2000 Mathematic Subject Classification: 05C20, 05C15.

## 1. Introduction

The heterochromatic number of an $r$-graph $H=(V, E)$ (hypergraph whose edges are sets of size $r$ ) is the minimum number $k$ such that each vertex colouring of $H$ using exactly $k$ colours leaves at least one edge all whose vertices receive different colours.

The heterochromatic number of $r$-graphs has been studied in several papers including general and particular settings (see for instance $[2]-[7]$ ). An important instance of this invariant is the heterochromatic number hc $(D)$ (with respect to $\vec{C}_{3}$ ) of a digraph $D$, which is the minimum integer $k$ such that for every partition of $V(D)$ into $k$ classes, there is a cyclic triangle whose
three vertices belong to different classes. The heterochromatic number is preserved under opposition (i.e., $h c\left(D^{o p}\right)=h c(D)$ where $D^{o p}$ denotes the digraph obtained from $D$ by reversing the direction of each arc of $D$ ).

Let $D_{n, s}$ be the oriented graph such that $V\left(D_{n, s}\right)$ is the set of integers $\bmod 2 n+1$ and $A\left(D_{n, s}\right)=\{(i, j): j-i \in\{1,2, \ldots n\} \backslash\{s\}\}$.

In this paper we prove that $h c\left(D_{n, s}\right) \leq 5$ for $n \geq 7$. The bound is tight since equality holds when $s \in\left\{n, \frac{2 n+1}{3}\right\}$. Related results concerning the heterochromatic number of circulant tournaments were given in [5] and [7].

## 2. Preliminaries

For general concepts we refer the reader to [1]. If $D$ is a digraph, $V(D)$ and $A(D)$ (or simply $A$ ) will denote the sets of vertices and arcs of $D$ respectively. A vertex $k$-colouring of $D$ is said to be full if it uses the $k$ colours. We will denote by $c_{1}, c_{2}, \ldots, c_{k}$ the colours and by $\mathfrak{C}_{1}, \mathfrak{C}_{2}, \ldots, \mathfrak{C}_{k}$ the corresponding chromatic classes. A heterochromatic cyclic triangle (h. triangle) is a cyclic triangle whose vertices are coloured with 3 different colours.

Along this paper we will work in the ring $Z_{2 n+1}$ of integers $\bmod 2 n+1$. If $J$ is a nonempty subset of $Z_{2 n+1} \backslash\{0\}$ such that $|\{j,-j\} \cap J| \leq 1$ for every $j \in Z_{2 n+1} \backslash\{0\}$ then the circulant oriented graph $\vec{C}_{2 n+1}(J)$ is defined by $V\left(\vec{C}_{2 n+1}(J)\right)=Z_{2 n+1}, A\left(\vec{C}_{2 n+1}(J)\right)=\left\{(i, j): i, j \in Z_{2 n+1}\right.$ and $\left.j-i \in J\right\}$ and $C_{2 n+1}(J)$ is its underlying graph. In particular, $\vec{C}_{2 n+1}=\vec{C}_{2 n+1}(\{1\})$ is the oriented cycle of length $2 n+1$ and $C_{2 n+1}$ is its underlying graph. Finally, for $S \subseteq I_{n}=\{1,2, \ldots, n\} \subseteq Z_{2 n+1}, \vec{C}_{2 n+1}\langle S\rangle$ will denote the circulant tournament $\vec{C}_{2 n+1}(J)$ where $J=\left(I_{n} \cup(-S)\right) \backslash S$ (when $S=\{s\}$ we will denote $\vec{C}_{2 n+1}\langle S\rangle$ by $\vec{C}_{2 n+1}\langle\langle \rangle)$.

The following statement is relevant in our approach.
Remark. Given any two different elements $i, j$ of $Z_{2 n+1}$, the reflection $\alpha_{i, j}$ of $C_{2 n+1}$ defined by $\alpha_{i, j}(x)=i+j-x$ is an antiautomorphism of $\vec{C}_{2 n+1}(J)$ which interchanges $i$ and $j$.
Although the aim of this work is to determine a tight upper bound for $h c\left(D_{n, s}\right)$, for technical reasons we prefer dealing with $\vec{C}_{2 n+1}\langle s\rangle$; so we define a normal triangle (n. triangle) of $\vec{C}_{2 n+1}\langle s\rangle$ to be a cyclic triangle in $\vec{C}_{2 n+1}\langle s\rangle$ avoiding the arcs of the form $(i+s, i)$, (i.e., a cyclic triangle of $D_{n, s}$ ).

We will write $\left(i \in \mathcal{C}_{1} \cup \mathfrak{C}_{2},(i, j, k, i)\right)$ to express that we may assume that $i \in \mathcal{C}_{1} \cup \mathcal{C}_{2}$ because $(i, j, k, i)$ is an heterochromatic normal triangle (h. n. triangle) whenever $i \notin \mathfrak{C}_{1} \cup \mathfrak{C}_{2}$.

Let $(j, k)$ be an arc of $\vec{C}_{2 n+1}\langle s\rangle$, along the proofs we will write $(j, k) \sim s$ or $s \sim(j, k)$ (resp. $(j, k) \nsim s$ or $s \nsim(j, k))$ to mean that $(j, k) \in\{(i+s, i) \mid i \in$ $\left.Z_{2 n+1}\right\}$ (resp. $\left.(j, k) \notin\left\{(i+s, i) \mid i \in Z_{2 n+1}\right\}\right)$. For a pair $(j, k)$, we write $s \nsim(j, k) \in A$ to mean that $(j, k) \in A$ and $(j, k) \nsim s$.

In what follows $\gamma_{n}(i, j)$ (or simply $\gamma(i, j)$ ) will denote the $i j$-path $(i, i+$ $1, \ldots, j)$ (notation $\bmod 2 n+1$ ) in $C_{2 n+1}$ as well as the set of its vertices; $\ell(\gamma(i, j))$ will be the length of $\gamma(i, j)$, i.e., the number of edges of $\gamma(i, j)$.

Two vertex colourings $f$ and $f^{\prime}$ of a digraph $D$ is said to be equivalent, in symbols: $f \equiv f^{\prime}$ when there exists either an automorphism or an antiautomorphism $\alpha$ of $D$ such that $f^{\prime}=f \circ \alpha$. Clearly $\equiv$ is an equivalence relation and $f$ and $f^{\prime}$ use the same colours whenever $f \equiv f^{\prime}$.

We will need the following two lemmas.
Lemma 2.1. Let $f$ and $f^{\prime}$ be vertex colourings of $\vec{C}_{2 n+1}\langle s\rangle$.
(i) If $f \equiv f^{\prime}$ and $f$ leaves an $h$. n. triangle of $\vec{C}_{2 n+1}\langle s\rangle$ then $f^{\prime}$ leaves an h. n. triangle of $\vec{C}_{2 n+1}\langle s\rangle$.
(ii) If $f^{\prime}=f \circ \alpha_{i, j}$, then $f^{\prime}\left(\alpha_{i, j}(x)\right)=f(x)$.

Lemma 2.2. Let $f$ be a full vertex $r$-colouring of $C_{2 n+1}$.
(i) Suppose $r \geq 4$. If (1) there exist two vertices $a, b \in V\left(C_{2 n+1}\right)$ with $\ell(\gamma(a, b))=n($ resp. $n-1)$ such that $a \in \mathcal{C}_{2}, b \in \mathcal{C}_{1}, \mathcal{C}_{3} \cap \gamma(a, b) \neq \emptyset$ and $\mathcal{C}_{4} \cap \gamma(a, b) \neq \emptyset$, then (2) there exist two vertices $a^{\prime}, b^{\prime} \in V\left(C_{2 n+1}\right)$ with $\ell\left(\gamma\left(a^{\prime}, b^{\prime}\right)\right)=n($ resp. $n-1)$ such that $a^{\prime} \in \mathcal{C}_{i}, b^{\prime} \in \mathcal{C}_{j}, \mathcal{C}_{k} \cap \gamma\left(b^{\prime}, a^{\prime}\right) \neq \emptyset$ and $\complement_{\ell} \cap \gamma\left(b^{\prime}, a^{\prime}\right) \neq \emptyset(\{i, j, k, \ell\}=\{1,2,3,4\})$.
(ii) If $r \geq 5$, then (2) holds.

Proof. To prove (i), take $c \in \mathcal{C}_{3} \cap \gamma(a, b)$ and $d \in \mathcal{C}_{4} \cap \gamma(a, b)$, and suppose that $c<d$ ( $c$ and $d$ considered as integers).

First consider $b+n$ (resp. $b+n-1$ ). Since $\mathcal{C}_{2} \cap \gamma(b+n, b) \neq \emptyset$, $\mathcal{C}_{3} \cap \gamma(b+n, b) \neq \emptyset$ and $\mathcal{C}_{4} \cap \gamma(b+n, b) \neq \emptyset$ we may assume $b+n$ (resp. $b+n-1) \in \mathcal{C}_{1}\left(\right.$ in other case we take $a^{\prime}=b$ and $b^{\prime}=b+n($ resp. $b+n-1)$ ). Now, since $c<d$ we have that colours $c_{1}, c_{2}$ and $c_{3}$ appear in $\gamma(d+n, d)$; so we may assume $d+n \in \mathcal{C}_{4}$. Finally we have that colours $c_{4}, c_{1}$ and $c_{2}$ appear in $\gamma(c+n, c)$ so we may assume $c+n \in \mathcal{C}_{3}$ and we obtain the vertices $a, b$ with $c+n \in \mathcal{C}_{3} \cap \gamma(b, a)$ and $d+n \in \mathcal{C}_{4} \cap \gamma(b, a)$ (resp. $d+n-1$ and $c+n-1)$.

In order to prove (ii), recall that the number of connected components of $C_{2 n+1}(\{s\})$ is the maximum common divisor of $s$ and $2 n+1$. In particular,
$C_{2 n+1}(\{n\})$ is connected and $C_{2 n+1}(\{n-1\})$ has either 1 or 3 connected components depending on whether $n \not \equiv 1$ or $n \equiv 1 \bmod 3$. Since $r=5$, $C_{2 n+1}$ has a vertex $i$ such that $i$ and $i+n$ (resp. $i+n-1$ ) have different colours. Applying (i) the proof ends.

## 3. An Upper Bound for $h_{c}\left(D_{n, s}\right)$.

In this section we give a tight upper bound for $h_{c}\left(D_{n, s}\right)$.
Theorem 3.1. For $n \geq 7$, every full vertex 5 -colouring of the circulant tournament $\vec{C}_{2 n+1}\langle s\rangle$ leaves an $h$. $n$. triangle; in other words $h c\left(D_{n, s}\right) \leq 5$ and equality holds whenever $s \in\left\{n, \frac{2 n+1}{3}\right\}$.

Proof. Consider any full vertex 5-colouring and suppose that no h. n. triangle is produced. We divide the proof into two cases.

Case 1. $s \neq n$.
Because of Lemmas 2.2(ii) and 2.1, we may assume that $0 \in \mathcal{C}_{1}$ and $n+1 \in$ $\mathcal{C}_{2}, \mathcal{C}_{3} \cap \gamma(0, n+1) \neq \emptyset$ and $\mathcal{C}_{4} \cap \gamma(0, n+1) \neq \emptyset$.

Let $i \in \mathcal{C}_{3} \cap \gamma(0, n+1)$ and $j \in \mathcal{C}_{4} \cap \gamma(0, n+1)$; we may assume that $|\{(n+1, i),(i, 0)\} \cap A|=1$ and $|\{(n+1, j),(j, 0)\} \cap A|=1$. If $|\{(n+1, i),(i, 0)\} \cap A|=0$, then $(0, i, n+1,0)$ is an h. n. triangle and if $|\{(n+1, i),(i, 0)\} \cap A|=2$, then $(0, j, n+1,0)$ is an h. n. triangle. Similarly $|\{(n+1, j),(j, 0)\} \cap A|=1$. Moreover $|\{(n+1, j),(n+1, i)\} \cap A|=1$ and $|\{(i, 0),(j, 0)\} \cap A|=1$. We may assume w.l.o.g. that $(i, 0) \in A$ (with $(i, 0) \sim s)$ and $(n+1, j) \in A$ (with $(n+1, j) \sim s)$. Now observe that when $\mathcal{C}_{5} \cap \gamma(0, n+1) \neq \emptyset,(0, k, n+1,0)$ is an h. n. triangle, where $k \in \mathcal{C}_{5} \cap \gamma(0, n+1)$. So we may assume that $\mathcal{C}_{5} \cap \gamma(0, n+1)=\emptyset$ and then $\mathcal{C}_{5} \cap \gamma(n+1,0) \neq \emptyset$.

Let $k \in \mathcal{C}_{5} \cap \gamma(n+1,0)$. We will analyze several possible cases.
Subcase 1.a. $s \nsim(j, k) \in A$.
$s \sim(0, k) \in A$. In other case $(0, j, k, 0)$ is an h. n. triangle $(s \nsim(0, j) \in A$ as $(i, 0) \sim s)$.

When $(i, k) \in A$ we have $(i, k) \nsim s$ (because $(i, 0) \sim s)$, also we have $2 s \geq n+1($ as $(i, 0) \sim s,(0, k) \sim s$ and $(i, k) \in A$ with $(i, k) \nsim s) ;$ so $s>1$; $\left(1 \in \mathcal{C}_{1} \cup \mathcal{C}_{2},(0,1, n+1,0)\right.$ ) (notice $\left.1 \neq s, n \neq s\right)$ and then $(i, k, 1, i)$ is an h. n. triangle. When $(k, i) \in A$ with $(k, i) \nsim s$ we have $2 s<n$ and hence $i<$ $j$; also we observe that $s \sim(j, i) \in A$ (in other case $(j, k, i, j)$ is an h. n. triangle and $s \sim(k, n+1) \in A$ (otherwise $(k, i, n+1, k)$ is an h. n. triangle;
so we obtain: $3 s=n+1((n+1, j) \sim s,(j, i) \sim s$ and $(i, 0) \sim s), 2 s=n$ $((0, k) \sim s$ and $(k, n+1) \sim s)$, so $s=1$ and $2 n+1=5$ contradicting $n \geq 7$. When $s \sim(k, i) \in A$ we have $j<i$ (because $(n+1, j) \sim s)$; in this case also we have $2 s>n+1$, so $s>1$ and $\left(1 \in \mathcal{C}_{1} \cup \mathfrak{C}_{2},(0,1, n+1,0)\right.$ ); we conclude that $(j, k, 1, j)$ is an h. n. triangle.

Subcase 1.b. $s \sim(j, k) \in A$.
Since $(n+1, j) \sim s$ and $(j, k) \sim s$ with $k \in \gamma(n+1,0)$ we have $2 s>n+1$ and hence $i>j$. Observe $(k, j+1) \in A$ (because $(j, k) \sim s<n)$. Now $n \in \mathcal{C}_{1} ;\left(n \in \mathfrak{C}_{1} \cup \mathfrak{C}_{2},(0, n, n+1,0)\right)$ and $\left(n \in \mathcal{C}_{1} \cup \mathfrak{C}_{5},(0, n, k, 0)\right)$. Consider $j+1$; when $j+1=i$ we get the h. n. triangle $(k, j+1, n+1, k)$ (Notice that $(n+1, k) \nsim s$ as $(j, k) \sim s$ and $n+1 \neq j$ since $(n+1, j) \sim s)$. When $j+1 \neq i$ we obtain $\left(j+1 \in \mathfrak{C}_{1} \cup \mathfrak{C}_{2},(0, j+1, n+1,0)\right)$, now if $j+1 \in \mathfrak{C}_{1}$ then $(j+1, n+1, k, j+1)$ is an h. n. triangle (we have observed that $(n+1, k) \nsim s)$ and if $j+1 \in \mathcal{C}_{2}$ then $(j+1, n, k, j+1)$ is an h. n. triangle (notice that $(n, k) \nsucc s$ because $(j, k) \sim s$ and $j \neq n$ as $j<i \in \gamma(0, n+1) \bigcap \mathcal{C}_{3}$ and $\left.n+1 \in \mathcal{C}_{2}\right)$.

Subcase 1.c. $(k, j) \in A$ (In this case $(k, j) \nsim s$ because $(n+1, j) \sim s)$. $s \neq 1$. If $s=1$ then $j=n$ but $(k, n) \notin A$ for every $k \in \gamma(n+1,0)$; so, $\left(n \in \mathcal{C}_{1} \cup \mathcal{C}_{2},(0, n, n+1,0)\right)$ and hence $(k, n) \sim s($ when $(n, k) \in A,(k, j, n, k)$ is an h. n. triangle). Now consider $n-1$ if $n-1=i$ then $(j, i, k, j)$ is an h. n. triangle and when $n-1 \neq i$ we have ( $n-1 \in \mathcal{C}_{1} \cup \mathcal{C}_{2},(0, n-1, n+1,0)$ ). (observe that since $(k, n) \sim s,(n+1, j) \sim s$ and $s \nsim(k, j) \in A$ we have $2 s-1>n+1 \geq 8$ so $s>2)$ and then $(k, j, n-1, k)$ is an h. n. triangle.
Finally, if $s=\frac{2 n+1}{3}$, the vertex 4-colouring defined by $\left(0 \in \mathfrak{C}_{1}, s \in \mathfrak{C}_{2}, 2 s \in\right.$ $\mathfrak{C}_{3}$ and $x \in \mathfrak{C}_{4}$ for $x \notin\{0, s, 2 s\}$ ) leaves no h. n. triangle and, since $s \neq n$, we obtain $h c\left(D_{n, s}\right)=5$.

Case 2. $s=n$.
Because of Lemmas 2.2(ii) and 2.1, we may assume that $n+2 \in \mathcal{C}_{2}, 0 \in \mathcal{C}_{1}$, $\mathfrak{C}_{3} \cap \gamma(0, n+2) \neq \emptyset$ and $\mathfrak{C}_{4} \cap \gamma(0, n+2) \neq \emptyset$.

For every $x \in \gamma(3, n-1), x \in \mathfrak{C}_{1} \cup \mathfrak{C}_{2}$. In other case ( $0, x, n+2,0$ ) is an h. n. triangle.

We may assume: $(1)\left(\mathcal{C}_{3} \cup \mathfrak{C}_{4}\right) \cap\{1,2\} \neq \emptyset\left(\right.$ when $\left(\mathfrak{C}_{3} \cup \mathcal{C}_{4}\right) \cap\{1,2\}=\emptyset$ we obtain $\left(\mathcal{C}_{3} \cup \mathcal{C}_{4}\right) \cap\{n, n+1\} \neq \emptyset$ and such a colouring is equivalent to another one satisfying (1) by Lemma 2.1(ii) where $\alpha_{i, j}=\alpha_{0, n+2}$ ). Suppose $\mathcal{C}_{5} \cap\{1,2, n, n+1\}=\emptyset$, then $\mathcal{C}_{5} \cap \gamma(n+2,0) \neq \emptyset$, let $k \in \mathcal{C}_{5} \cap \gamma(n+2,0)$ and
let $i \in\{1,2\} \cap\left(\mathcal{C}_{3} \cup \mathcal{C}_{4}\right)$. If $k \in \gamma(n+4,2 n-2)$ or if $(k=3$ and $i=1)$ then $(i, n-1, k, i)$ is an h. n. triangle; now suppose $k=n+3$ and $i=2$; clearly we may assume $1 \in \mathcal{C}_{1} \cup \mathcal{C}_{2}$ (otherwise ( $1, n-1, n+3,1$ ) is an h. n. triangle), also we may assume $n+1 \in \mathcal{C}_{4}$ (otherwise $n \in \mathcal{C}_{4}$ and $(1, n, n+3,1)$ is an h. n. triangle), moreover $n+5 \in \mathcal{C}_{3}\left(\left(n+5 \in \mathcal{C}_{1} \cup \mathcal{C}_{2} \cup \mathcal{C}_{3},(2, n-1, n+5,2)\right)\right.$ and $\left.\left(n+5 \in \mathcal{C}_{3} \cup \mathcal{C}_{4},(2, n+1, n+5,2)\right)\right)$, so $(2, n+1, n+5,2)$ is an h. n. triangle. Hence $k \in\{2 n, 2 n-1\}$ (notice that $k \neq n+2$ as $n+2 \in \mathcal{C}_{2}$ and $k \in \mathcal{C}_{5}$ ). If $i=2$ we have $\left(n+1 \in \mathcal{C}_{3} \cup \mathfrak{C}_{4} \cup \mathfrak{C}_{5},(i, n+1, k, i)\right)$ (notice that $i \in \mathcal{C}_{3} \cup \mathcal{C}_{4}$ and $k \in \mathcal{C}_{5}$ ); when $n+1 \in \mathcal{C}_{5}$ we are done, so $n+1 \in \mathcal{C}_{3} \cup \mathcal{C}_{4}$ and then $(n+1, k, 3, n+1)$ is an h. n. triangle; we conclude that $i=1$ and $2 \notin \mathcal{C}_{3} \cup \mathfrak{C}_{4} \cup \mathcal{C}_{5}$, and so $\{n, n+1\} \cap\left(\mathcal{C}_{3} \cup \mathcal{C}_{4}\right) \neq \emptyset$; moreover, again by Lemma 2.1(ii) we may assume that $n \notin\left(\mathcal{C}_{3} \cup \mathcal{C}_{4} \cup \mathcal{C}_{5}\right), 1 \in \mathcal{C}_{3}$ and $n+1 \in \mathcal{C}_{4}$ and then $(n+1, k, 3, n+1)$ is an h. n. triangle.

Suppose now that $\mathcal{C}_{5} \cap\{1,2, n, n+1\} \neq \emptyset$ it follows that there exists an $\operatorname{arc}(a, b)$ with $a \in\{1,2\}, b \in\{n, n+1\}, \ell(\gamma(a, b))=n-1, a \in \mathcal{C}_{i}, b \in \mathcal{C}_{j}$ and $\{i, j\} \in\{3,4,5\}$ without loss of generality assume $1 \in \mathcal{C}_{3}$ and $n \in \mathcal{C}_{4}$ (the other possible cases are completly analogous). Now $\left(n+5 \in \mathcal{C}_{3} \cup \mathcal{C}_{4}\right.$, $(1, n, n+5,1))$ (remember $n \geq 7$ ) and $\{2, n+1\} \cap \mathcal{C}_{5} \neq \emptyset$. When $2 \in \mathcal{C}_{5}$ we get $(n+5,2, n-1, n+5)$ an h. n. triangle and when $n+1 \in \mathcal{C}_{5}$ we obtain the h. n. triangle $(n+1, n+5,3, n+1)$.

Finally, since the vertex 4-colouring of $D_{n, n}$ defined by $\left(0 \in \mathcal{C}_{1}, n \in \mathcal{C}_{2}, n+\right.$ $1 \in \mathcal{C}_{3}$ and $x \in \mathcal{C}_{4}$ for $x \notin\{0, n, n+1\}$ ) leaves no h. n. triangle, we obtain $h c\left(D_{n, n}\right)=5$.

## 4. Final Comment

It can be proved that $h c\left(D_{n, s}\right)=4$ whenever $n \geq 7$ and $s \notin\{n,(2 n+1) / 3\}$. The complete determination of $h c\left(D_{n, s}\right)$, which is a useful tool in studying 4-heterochromatic cycles in circulant tournaments, requires an extense proof and will be given elsewhere.

## Acknowledgement

We thank the referee for his useful comments which contributed to improve the final version of this paper.
