# ESTIMATION OF CUT-VERTICES IN EDGE-COLOURED COMPLETE GRAPHS 

ADAM IDZIK<br>Akademia Świȩtokrzyska<br>15 Świȩtokrzyska street, 25-406 Kielce, Poland<br>and<br>Institute of Computer Science<br>Polish Academy of Sciences<br>21 Ordona street, 01-237 Warsaw, Poland<br>e-mail: adidzik@ipipan.waw.pl

All graphs considered here are finite simple graphs, i.e., graphs without loops, multiple edges or directed edges. For a graph $G=(V, E)$, where $V$ is a vertex set and $E$ is an edge set, we write sometimes $V(G)$ for $V$ and $E(G)$ for $E$ to avoid ambiguity. We shall write $G \backslash v$ instead of $G_{V \backslash\{v\}}=$ ( $V \backslash\{v\}, E \cap 2^{V \backslash\{v\}}$ ), the subgraph induced by $V \backslash\{v\}$. A vertex $v \in V(G)$ is called a cut-vertex of $G$ if $G$ is connected and $G \backslash v$ is not. By a $k$-edgecolouring of a graph we mean any finite partition of the set of its edges into $k$ subsets. A graph $(V, E)$ with a given $k$-edge-colouring $\left(E^{1}, \cdots, E^{k}\right)$ $\left(E^{i} \cap E^{j}=\emptyset\right.$ for $i \neq j ; i, j \in\{1, \cdots, k\}$ and $\left.\bigcup_{i \in\{1, \cdots, k\}} E^{i}=E\right)$ is denoted by $\left(V, E^{1}, \cdots, E^{k}\right)$. The graphs $\left(V, E^{i}\right)$ are called monochromatic subgraphs of ( $V, E^{1}, \cdots, E^{k}$ ), $i \in\{1, \cdots, k\}$. As usual, by $K_{m}$ we denote the complete graph with $m$ vertices.

Let $\mathrm{c}\left(G^{i}\right)$ denote the number of cut-vertices of $G^{i}$ in a monochromatic subgraph $G^{i}=\left(V, E^{i}\right)$ of a $k$-edge-coloured complete graph $K_{m}=\left(V, E^{1}\right.$, $\left.\cdots, E^{k}\right)(i \in\{1, \cdots, k\})$.

Given a $k$-edge-coloured graph $G=\left(V, E^{1}, \cdots, E^{k}\right)$, we define $F^{i}=E \backslash$ $E^{i}, G^{i}=\left(V, E^{i}\right), \bar{G}^{i}=\left(V, F^{i}\right)$, where $E=\bigcup_{i \in\{1, \cdots, k\}} E^{i}$ and $i \in\{1, \cdots, k\}$. Here $G^{i}$ is a monochromatic subgraph of $G$ and $\bar{G}^{i}$ its complement in $G$.

Theorem (Idzik, Tuza, Zhu). Let ( $\left.E^{1}, \cdots, E^{k}\right)$ be a $k$-edge-colouring of $K_{m}$ ( $k \geq 2, m \geq 4$ ), such that all the graphs $\bar{G}^{1}, \cdots, \bar{G}^{k}$ are connected.
(i) If one of the subgraphs $G^{1}, \cdots, G^{k}$ is 2 -connected, say $G^{i}$, then $c\left(\bar{G}^{i}\right) \leq$ $m-2$ and $c\left(\bar{G}^{j}\right)=0$ for $j \neq i(i, j \in\{1, \ldots, k\})$.
(ii) If none of the graphs $G^{1}, \cdots, G^{k}$ is 2-connected, and one of them is connected, say $G^{i}$, then $c\left(\bar{G}^{i}\right) \leq 2(i \in\{1, \cdots, k\})$.
(iii) If none of the graphs $G^{1}, \cdots, G^{k}$ is 2 -connected, and one of them is disconnected, say $G^{i}$, then $c\left(\bar{G}^{i}\right) \leq 1(i \in\{1, \cdots, k\})$.

Problem. Let $\left(E^{1}, \cdots, E^{k}\right)$ be a $k$-edge-colouring of $K_{m}(k \geq 2, m \geq 4)$. What is the cardinality of the set of the sum of cut-vertices of $\overline{\bar{G}}^{i}$ in the case none of $G^{i}$ is 2-connected and (a) two of $G^{i}$ are connected or (b) two of $G^{i}$ are disconnected and $c\left(\bar{G}^{i}\right)=1(i \in\{1, \cdots, k\})$ ?

Observe that in both cases (a) and (b) all the graphs $\bar{G}^{1}, \cdots, \bar{G}^{k}$ are connected.

This problem is related to some theorems presented in [1] and [2].
