#### Abstract

Let $p$ be a positive integer and $G=(V, E)$ a graph. A subset $S$ of $V$ is a $p$-dominating set if every vertex of $V-S$ is dominated at least $p$ times. The minimum cardinality of a $p$-dominating set a of $G$ is the $p$-domination number $\gamma_{p}(G)$. It is proved for a cactus graph $G$ that $\gamma_{p}(G) \leqslant\left(|V|+\left|L_{p}(G)\right|+c(G)\right) / 2$, for every positive integer $p \geqslant 2$, where $L_{p}(G)$ is the set of vertices of $G$ of degree at most $p-1$ and $c(G)$ is the number of odd cycles in $G$.

Keywords: p-domination number, cactus graphs.
2000 Mathematics Subject Classification: 05C69.

## 1. Introduction

Let $G=(V(G), E(G))$ be a graph with vertex set $V(G)$ and edge set $E(G)$. The order of $G$ is $n(G)=|V(G)|$ and the degree of a vertex $v$, denoted by $\operatorname{deg}_{G}(v)$, is the number of vertices adjacent to $v$. A vertex of degree one is called a leaf and its neighbor is called a support vertex. A vertex of $V$ is called a cut vertex if removing it from $G$ increases the number of components of $G$. A graph $G$ is called a cactus graph if each edge of $G$ is contained in at most one cycle. A unicycle graph is a graph with exactly one cycle. A tree $T$ is a double star if it contains exactly two vertices that are not leaves. A double star with, respectively $p$ and $q$ leaves attached at each support vertex, is denoted by $S_{p, q}$.

For a positive integer $p$, a subset $S$ of $V(G)$ is a $p$-dominating set if every vertex not in $S$ is adjacent to at least $p$ vertices of $S$. The $p$-domination number $\gamma_{p}(G)$ is the minimum cardinality of a $p$-dominating set of $G$. Note that every graph $G$ has a $p$-dominating set, since $V(G)$ is such a set. Also the 1-domination number $\gamma_{1}(G)$ is the usual domination number $\gamma(G)$. The concept of $p$-domination was introduced by Fink and Jacobson [2, 3]. For more details on domination and its variations see the books of Haynes, Hedetniemi, and Slater [4, 5].

We make a straightforward observation.

Observation 1. Every $p$-dominating set of a graph $G$ contains any vertex of degree at most $p-1$.

In this paper we present an upper bound for the $p$-domination number for cactus graphs in terms of the order, the number of odd cycles and the number of vertices of degrees at most $p-1$.

The following result due to Blidia et al. [1] will be useful for the next. Let $L_{p}(G)$ denote the set $\left\{x \in V(G): \operatorname{deg}_{G}(x) \leqslant p-1\right\}$.

Theorem 2 (Blidia, Chellali and Volkmann [1]). Let p be a positive integer. If $G$ is a bipartite graph then

$$
\gamma_{p}(G) \leqslant\left(n+\left|L_{p}(G)\right|\right) / 2
$$

## 2. Main Results

We begin by giving an upper bound for the $p$-domination number for connected unicycle graphs.

Theorem 3. Let $p \geqslant 2$ be a positive integer. If $G$ is a connected unicycle graph then

$$
\gamma_{p}(G) \leqslant\left(n+\left|L_{p}(G)\right|+1\right) / 2
$$

and this bound is sharp.
Proof. Let $G$ be a connected unicycle graph. If $G$ is bipartite then the result is valid by Theorem 2. So assume that $G$ contains an odd cycle denoted by $C$. If $G=C$, then $\gamma_{p}(G)=n$ if $p \geqslant 3$ and $\gamma_{p}(G)=(n+1) / 2$ if $p=2$, in both cases the result holds. Thus we assume that $G \neq C$, that is $G$ contains at least one leaf.

Suppose that the result does not hold and let $G$ be the smallest connected unicycle graph such that $\gamma_{p}(G)>\left(n+\left|L_{p}(G)\right|+1\right) / 2$. We claim that every vertex on $C$ has degree exactly $p$. Suppose to the contrary that there is a vertex $x \in C$ such that $\operatorname{deg}_{G}(x) \neq p$ and let $y$ be one of its two neighbors on $C$. Let $G^{\prime}$ be the spanning graph of $G$ obtained by removing the edge $x y$. Then $G^{\prime}$ is tree and so a bipartite graph. We also have $\left|L_{p}\left(G^{\prime}\right)\right| \leqslant\left|L_{p}(G)\right|+1$ and $n(G)=n\left(G^{\prime}\right)$. According to Theorem 2, we deduce that

$$
\gamma_{p}(G) \leqslant \gamma_{p}\left(G^{\prime}\right) \leqslant\left(n\left(G^{\prime}\right)+\left|L_{p}\left(G^{\prime}\right)\right|\right) / 2 \leqslant\left(n(G)+\left|L_{p}(G)\right|+1\right) / 2
$$

a contradiction with our assumption.
Similarly, we will show that every vertex not on $C$ and different to a leaf has degree at least $p$. Assume to the contrary that there is a vertex $x \in V(G)-C$ different to a leaf with $\operatorname{deg}_{G}(x) \leqslant p-1$ and let $z$ be its neighbor in the unique path from $x$ to $C$. Let $G_{1}$ be the connected unicycle subgraph of $G$ containing $x$ and obtained by removing all the edges incident to $x$ excepted the edge $x z$, and let $G_{2}$ be the component containing $x$ by removing the edge $x z$. Let $D_{1}$ and $D_{2}$ denote a $\gamma_{p}\left(G_{1}\right)$-set and a $\gamma_{p}\left(G_{2}\right)$ set, respectively. Clearly $G_{1}$ contains $C$ and $G_{2}$ is a tree, $x \in D_{1} \cap D_{2}$, $x \in L_{p}\left(G_{1}\right) \cap L_{p}\left(G_{2}\right),\left|L_{p}\left(G_{1}\right)\right|+\left|L_{p}\left(G_{2}\right)\right|=\left|L_{p}(G)\right|+1$ and $n\left(G_{1}\right)+n\left(G_{2}\right)=$ $n(G)+1$. Furthermore, $D_{1} \cup D_{2}$ is a $p$-dominating set of $G$. In addition, $G_{1}$ and $G_{2}$ have order less than $G$ and so satisfy the theorem, implying that

$$
\begin{aligned}
\gamma_{p}(G) & \leqslant\left|D_{1} \cup D_{2}\right|=\gamma_{p}\left(G_{1}\right)+\gamma_{p}\left(G_{2}\right)-1 \\
& \leqslant\left(n\left(G_{1}\right)+\left|L_{p}\left(G_{1}\right)\right|+1\right) / 2+\left(n\left(G_{2}\right)+\left|L_{p}\left(G_{2}\right)\right|\right) / 2-1 \\
& \leqslant\left(n+\left|L_{p}(G)\right|+1\right) / 2
\end{aligned}
$$

contradicting the assumption.

Suppose now that $V(G)-C$ contains a support vertex. Let $a$ be a support vertex of $G$ of maximum distance from $C$. As seen above, $a$ has degree at least $p$. Let $G^{\prime}=G-\left(L_{a} \cup\{a\}\right)$. Then $\gamma_{p}\left(G^{\prime}\right)+\left|L_{a}\right|=\gamma_{p}(G), n\left(G^{\prime}\right)=$ $n(G)-\left|L_{a}\right|-1$ and $L_{p}(G) \geqslant L_{p}\left(G^{\prime}\right)+\left|L_{a}\right|-1$. It follows that

$$
\gamma_{p}\left(G^{\prime}\right)+\left|L_{a}\right|=\gamma_{p}(G)>\left(n(G)+\left|L_{p}(G)\right|+1\right) / 2
$$

implying that

$$
\gamma_{p}\left(G^{\prime}\right)>\left(n(G)+\left|L_{p}(G)\right|+1-2\left|L_{a}\right|\right) / 2
$$

and so

$$
\gamma_{p}\left(G^{\prime}\right)>\left(n\left(G^{\prime}\right)+\left|L_{p}\left(G^{\prime}\right)\right|+1\right) / 2
$$

contradicting our assumption that $G$ is the smallest graph that does not satisfy the theorem.

Consequently, every vertex of $V(G)-C$ must be a leaf and so every vertex on $C$ is adjacent to exactly $p-2$ leaves, which implies that

$$
\gamma_{p}(G)=n-(|V(C)|-1) / 2=\left(n(G)+\left|L_{p}(G)\right|+1\right) / 2
$$

a contradiction.
To see that this bound is sharp, consider the graph $G$ formed by an odd cycle $C$ where each vertex on $C$ is adjacent to exactly $p-2$ vertices. Then $\gamma_{p}(G)=n-(|V(C)|-1) / 2=\left(n(G)+\left|L_{p}(G)\right|+1\right) / 2$.

Theorem 4. Let $p \geqslant 2$ be a positive integer. If $G$ is a connected cactus graph with $c(G)$ odd cycles then,

$$
\gamma_{p}(G) \leqslant\left(n+\left|L_{p}(G)\right|+c(G)\right) / 2,
$$

and this bound is sharp.
Proof. If $G$ is a bipartite graph, then by Theorem 2 the result holds. If $G$ is a unicycle graph then by Theorem 3 the result is also valid. So consider a cactus graph $G$ containing at least two cycles with one of odd length. Assume that the result does not hold and let $G$ be the smallest cactus graph such that $\gamma_{p}(G)>\left(n(G)+\left|L_{p}(G)\right|+c(G)\right) / 2$. We also assume that among all such graphs, $G$ is the one having the fewest edges.

First, let $u$ be a vertex on an odd cycle $C$ of $G$ and assume that $\operatorname{deg}_{G}(u) \neq p$. Let $G^{\prime}$ be the spanning graph of $G$ obtained by removing an
edge of $C$ incident with $u$. Then $\left|L_{p}\left(G^{\prime}\right)\right| \leqslant\left|L_{p}(G)\right|+1$ and $c\left(G^{\prime}\right)=c(G)-1$. Also $G^{\prime}$ satisfies the result and so

$$
\begin{aligned}
\gamma_{p}(G) & \leqslant \gamma_{p}\left(G^{\prime}\right) \leqslant\left(n\left(G^{\prime}\right)+\left|L_{p}\left(G^{\prime}\right)\right|+c\left(G^{\prime}\right)\right) / 2 \\
& \leqslant\left(n(G)+\left|L_{p}(G)\right|+1+c(G)-1\right) / 2=\left(n+\left|L_{p}(G)\right|+c(G)\right) / 2
\end{aligned}
$$

a contradiction. Thus every vertex in an odd cycle has degree exactly $p$.
Now consider a vertex $v$ different from a leaf and contained in no odd cycle. Then, either $v$ is a cut vertex or $v$ is on an even cycle and $\operatorname{deg}_{G}(v)=2$. Suppose first that $v$ is a cut vertex with $\operatorname{deg}_{G}(v)<p$. Let $G_{1}$ and $G_{2}$ be two connected cactus subgraphs of $G$ with $V(G)=V\left(G_{1}\right) \cup V\left(G_{2}\right)$ having $v$ as a unique common vertex. Then, $c(G)=c\left(G_{1}\right)+c\left(G_{2}\right), n(G)=n\left(G_{1}\right)+$ $n\left(G_{2}\right)-1,\left|L_{p}(G)\right|=\left|L_{p}\left(G_{1}\right)\right|+\left|L_{p}\left(G_{2}\right)\right|-1$. Now let $D_{1}$ and $D_{2}$ denote a $\gamma_{p}\left(G_{1}\right)$-set and a $\gamma_{p}\left(G_{2}\right)$-set, respectively. Then $v \in D_{1} \cup D_{2}$ and $D_{1} \cup D_{2}$ is a $p$-dominating set of $G$. Since $G_{1}$ and $G_{2}$ satisfy the result,

$$
\begin{aligned}
\gamma_{p}(G) & \leqslant\left|D_{1} \cup D_{2}\right|=\left|D_{1}\right|+\left|D_{2}\right|-1 \\
& \leqslant\left(n\left(G_{1}\right)+\left|L_{p}\left(G_{1}\right)\right|+c\left(G_{1}\right)\right) / 2+\left(n\left(G_{2}\right)+\left|L_{p}\left(G_{2}\right)\right|+c\left(G_{2}\right)\right) / 2-1 \\
& \leqslant\left(n(G)+\left|L_{p}(G)\right|+c(G)\right) / 2
\end{aligned}
$$

a contradiction. Consequently, every cut vertex contained in no odd cycle has degree at least $p$.

Now let $v$ be a vertex on an even cycle with $\operatorname{deg}_{G}(v)=2$. Since we have assumed in the beginning of the proof that $G$ has at least two cycles, we have $p \geqslant 3$. We claim that each neighbor of $v$ has degree exactly $p$. Indeed, let $u$ be a neighbor of $v$ and assume that $\operatorname{deg}_{G}(u) \neq p$. Then every $\gamma_{p}\left(G^{\prime}\right)$-set $S$ is a $p$-dominating set of $G$ where $G^{\prime}$ is obtained from $G$ by removing the edge $v u$. So

$$
\gamma_{p}(G) \leqslant|S| \leqslant\left(n\left(G^{\prime}\right)+\left|L_{p}\left(G^{\prime}\right)\right|+c\left(G^{\prime}\right)\right) / 2=\left(n(G)+\left|L_{p}(G)\right|+c(G)\right) / 2
$$

a contradiction. Thus $\operatorname{deg}_{G}(u)=p$.
Now let $C$ denote an odd cycle of length at least 5 and let $w$ be a vertex on $C, a$ and $b$ its neighbors on $C$. Delete the edges $w a, w b$. The remaining graph has two components for otherwise $w a$ or $w b$ would be contained in two cycles. Let $G_{1}$ be the component containing $w$ and $G_{2}$ the other component where a new edge is added joining $a$ and $b$. Then both $G_{1}$ and $G_{2}$ verify the theorem. Also $\operatorname{deg}_{G_{2}}(a)=\operatorname{deg}_{G_{2}}(b)=p,\left|L_{p}\left(G_{1}\right)\right|+\left|L_{p}\left(G_{2}\right)\right| \leqslant\left|L_{p}(G)\right|+1$
and $c\left(G_{1}\right)+c\left(G_{2}\right)=c(G)-1$. Let $D_{1}$ and $D_{2}$ be a $\gamma_{p}\left(G_{1}\right)$-set and a $\gamma_{p}\left(G_{2}\right)$ set, respectively. Then $D_{1}$ contains $w$ since $\operatorname{deg}_{G_{1}}(w)=p-2$. It can be checked that $D_{1} \cup D_{2}$ is a $p$-dominating set of $G$. It follows that

$$
\begin{aligned}
\gamma_{p}(G) & \leqslant\left|D_{1} \cup D_{2}\right| \\
& \leqslant\left(n\left(G_{1}\right)+\left|L_{p}\left(G_{1}\right)\right|+c\left(G_{1}\right)\right) / 2+\left(n\left(G_{2}\right)+\left|L_{p}\left(G_{2}\right)\right|+c\left(G_{2}\right)\right) / 2 \\
& \leqslant\left(n(G)+\left|L_{p}(G)\right|+1+c(G)-1\right) / 2=\left(n(G)+\left|L_{p}(G)\right|+c(G)\right) / 2
\end{aligned}
$$

contradicting our assumption. Thus it remains to investigate the case that each odd cycle is a triangle.

Let $C=u v w$ be a triangle of $G$. If $p=2$ then as claimed before $G=C_{3}$ and the theorem is valid. So assume that $p \geqslant 3$. Let $G_{u}, G_{v}$ and $G_{w}$ be the three components of $G$ containing $u, v, w$, respectively, by removing the edges $u v, u w$ and $v w$. Suppose that each component contains at most one vertex of degree at least $p$ and let $j$ the number of vertices of degree at least $p$ in the three components. Then $j \leqslant 3$ and $\left|L_{p}(G)\right|=n-3-j$. In this case, $G_{u}$ is either a star of center vertex $u$ with $p-2$ leaves, or star of order at least 4 where $u$ is a leaf if $p=3$, or a double star $S_{p-3, p-1}$ with $u$ as a support vertex if $p \geqslant 4$, or a graph formed by a cycle $C_{4}$ where $u \in V\left(C_{4}\right)$ and is adjacent to $p-4$ leaves (if $p \geqslant 4$ ), its neighbors on the cycle have degree 2 and the remaining vertex of the cycle is adjacent to $p-2$ leaves. Likewise $G_{v}$ and $G_{w}$. If each component is a tree then $G$ is a unicycle and the result follows by Theorem 3. So we assume that $G_{u}$ is a component containing the cycle $C_{4}$. Now it is a routine matter to check that

$$
\gamma_{p}(G)=n-(j+1) \leqslant\left(n(G)+\left|L_{p}(G)\right|+c(G)\right) / 2=n-1-j / 2,
$$

a contradiction.
Thus we may assume, without loss of generality, that $G_{u}$ contains at least two vertices of degree at least $p$. Let $G^{\prime}$ be the component containing $v, w$ by removing the edges $u v, u w$. Let $G_{0}$ be the graph constructed from $G^{\prime}$ by attaching $v$ and $w$ to the support vertices say $a, b$ of a double star $S_{p-2, p-2}$ (so $v, w, a, b$ induce a cycle $C_{4}$ ) and let $D_{u}$ and $D_{0}$ a $\gamma_{p}\left(G_{u}\right)$-set and a $\gamma_{p}\left(G_{0}\right)$-set, respectively. Then, without loss of generality, $D_{0}$ contains $v, w, a$ all the leaves adjacent to $a$ and $b$. Also $D_{u}$ contains $u$ since it has degree at most $p-2$. Obviously $D_{u} \cup\left(D_{0}-\left(\{a\} \cup L_{a} \cup L_{b}\right)\right)$ is a $p$-dominating set of $G$. It is easy to check that $G_{u}$ contains at least $2 p-1$ vertices. Thus $G_{0}$ has order less than $G$ since we have added $2 p-2$ vertices and so both
$G_{u}, G_{0}$ verify the result. On the other hand, $n(G)=n\left(G_{u}\right)+n\left(G_{0}\right)-2 p+2$, $L_{p}(G)=L_{p}\left(G_{u}\right)-1+L_{p}\left(G_{0}\right)-2 p+4, c(G)=c\left(G_{u}\right)+c\left(G_{0}\right)+1$. Consequently

$$
\begin{aligned}
\gamma_{p}(G) \leqslant & \left|D_{u} \cup\left(D_{0}-\left(\{a\} \cup L_{a} \cup L_{b}\right)\right)\right|=\gamma_{p}\left(G_{u}\right)+\gamma_{p}\left(G_{0}\right)-2 p+3 \\
\leqslant & \left(n\left(G_{u}\right)+\left|L_{p}\left(G_{u}\right)\right|+c\left(G_{u}\right)\right) / 2 \\
& +\left(n\left(G_{0}\right)+\left|L_{p}\left(G_{0}\right)\right|+c\left(G_{0}\right)\right) / 2-2 p+3 \\
\leqslant & \left(n(G)+\left|L_{p}(G)\right|+c(G)\right) / 2,
\end{aligned}
$$

a contradiction with our assumption.
That this bound is sharp may be seen by considering the graph $G_{k}$ formed by $k \geqslant 1$ triangles where each vertex of the triangle is attached to $p-2$ leaves, and identifying a vertex of every triangle with a vertex of a path $P_{k}$. Then $n\left(G_{k}\right)=(3 p-3) k,\left|L_{p}\left(G_{k}\right)\right|=3(p-2) k, c\left(G_{k}\right)=k$ and $\gamma_{p}(G)=\left(n\left(G_{k}\right)+\left|L_{p}\left(G_{k}\right)\right|+c\left(G_{k}\right)\right) / 2=(3 p-4) k$.
