#### Abstract

The edge $C_{4}$ graph of a graph $G, E_{4}(G)$ is a graph whose vertices are the edges of $G$ and two vertices in $E_{4}(G)$ are adjacent if the corresponding edges in $G$ are either incident or are opposite edges of some $C_{4}$. In this paper, we show that there exist infinitely many pairs of non isomorphic graphs whose edge $C_{4}$ graphs are isomorphic. We study the relationship between the diameter, radius and domination number of $G$ and those of $E_{4}(G)$. It is shown that for any graph $G$ without isolated vertices, there exists a super graph $H$ such that $C(H)=G$ and $C\left(E_{4}(H)\right)=E_{4}(G)$. Also we give forbidden subgraph characterizations for $E_{4}(G)$ being a threshold graph, block graph, geodetic graph and weakly geodetic graph.

Keywords: edge $C_{4}$ graph, threshold graph, block graph, geodetic graph, weakly geodetic graph.
2010 Mathematics Subject Classification: 05C99.

## 1. Introduction

We consider the graph operator $E_{4}(G)$, whose vertices are the edges of $G$ and two vertices in $E_{4}(G)$ are adjacent if the corresponding edges in $G$ are either incident or are opposite edges of some $C_{4}$. This graph class is also known by the name edge graph in [11]. In $E_{4}(G)$ any two vertices are adjacent if the union of the corresponding edges in $G$ induce any one of the graphs $P_{3}, C_{3}, C_{4}, K_{4}-\{e\}, K_{4}$. If $a_{1}-a_{2}$ is an edge in $G$, the corresponding
vertex in $E_{4}(G)$ is denoted by $a_{1} a_{2}$. In [9], we obtained characterizations for $E_{4}(G)$ being connected, complete, bipartite etc and also some dynamical behaviour of $E_{4}(G)$ are studied. It was also proved that $E_{4}(G)$ has no forbidden subgraphs.

For a vertex $v \in V(G), N(v)$ denotes the set of all vertices in $G$ which are adjacent to $v$ and $N[v]=N(v) \cup\{v\}$. A vertex $x$ dominates a vertex $y$ if $N(y) \subseteq N[x]$. If $x$ dominates $y$ or $y$ dominates $x$, then $x$ and $y$ are comparable. Otherwise, they are incomparable. The Dilworth number of a graph $G, \operatorname{dilw}(G)$ is the largest number of pairwise incomparable vertices of $G$. A vertex $v$ is a universal vertex if it is adjacent to all the other vertices in $G$. A subset $S$ of $V$ is a dominating set if each vertex of $G$ that is not in $S$ is adjacent to at least one vertex of $S$. If $S$ is a dominating set then $N[S]=V$. A dominating set of minimum cardinality is called a minimum dominating set, its cardinality is called the domination number of $G$ and it is denoted by $\gamma(G)$. Many types of domination and its characteristics are discussed in [5]. In [4], it is observed that for graphs $G$ without isolated vertices, $\gamma(G) \leq \operatorname{dilw}(G)$.

All the graphs considered here are finite, undirected and simple. We denote by $P_{n}$ (respectively $C_{n}$ ), a path (respectively cycle) on $n$ vertices. The graph obtained by deleting any edge ' $e$ ' of $K_{n}$ is denoted by $K_{n}-\{e\}$. The join of two graphs $G=\left(V_{1}, E_{1}\right)$ and $H=\left(V_{2}, E_{2}\right)$ is denoted by $G \vee H$ and has $V(G \vee H)=V_{1} \cup V_{2}$ and $E(G \vee H)=E_{1} \cup E_{2} \cup\left\{(u, v): u \in V_{1}\right.$ and $\left.v \in V_{2}\right\}$. A 'bow' is $K_{1} \vee 2 K_{2}$. The graph obtained by attaching a pendant vertex to any vertex of $C_{n}$, is called an ' $n$-pan' and a 'paw' is a 3 -pan. The graph in Figure 1 is called a 'moth'.

Figure 1
A graph $G$ is $H$-free if $G$ does not contain $H$ as an induced subgraph. A graph $H$ is a forbidden subgraph for a property $P$, if any graph $G$ which satisfies the property $P$ cannot have $H$ as an induced subgraph. The distance between any two vertices $u$ and $v$ of a connected graph $G, d_{G}(u, v)$ is the
length of a shortest path joining them. The eccentricity of a vertex $v \in V(G)$ is $e(v)=\max \{d(u, v): u \in V(G)\}$. The radius and diameter of $G$ are respectively $\operatorname{rad}(G)=\min \{e(v): v \in V(G)\}, \operatorname{diam}(G)=\max \{e(v): v \in$ $V(G)\}$. A vertex $v$ is called a central vertex of $G$ if $e(v)=\operatorname{rad}(G)$. The center, $C(G)$ of a connected graph $G$ is the subgraph of $G$ induced by its central vertices. The girth of $G, g(G)$ is the length of a shortest cycle in $G$. A clique in $G$ is a complete subgraph of $G$. For all basic concepts and notations not mentioned in this paper we refer [13].

The line graph $L(G)$ of a graph $G$ is a graph that has a vertex for every edge of $G$, and two vertices of $L(G)$ are adjacent if and only if they correspond to two edges of $G$ with a common end vertex. In [8], it is shown that for any graph $G$ without isolated vertices, there is a graph $H$ such that $C(H)=G$ and $C(L(H))=L(G)$. It is further proved that $\operatorname{diam}(L(G)) \leq$ $\operatorname{diam}(G)+1$ and $\operatorname{rad}(L(G)) \leq \operatorname{rad}(G)+1$.

In [1], several graph classes and their forbidden subgraph characterizations for many properties are discussed in detail. We consider the graph classes - threshold graphs, cographs, block graphs, geodetic graphs and weakly geodetic graphs with regard to $E_{4}(G)$.

Threshold graphs were introduced by Chvátal and Hammer in [2]. It is known that a graph $G$ is a threshold graph if and only if $\operatorname{dilw}(G)=1$ and that $G$ is $\left\{2 K_{2}, C_{4}, P_{4}\right\}$-free graph $[2,5]$.

In [7], it is proved that a connected graph $G$ is a block graph if and only if every maximal 2 -connected subgraph (block) is complete. A cycle $C$ of $G$ is a $b$-cycle of $G$ if $C$ is not contained in a clique of $G$. The bulge of $G$, $b(G)$ is the minimum length of a $b$-cycle in $G$ if $G$ contains a $b$-cycle and is $\infty$ otherwise. Also, $G$ is a block graph if and only if $b(G)=\infty[6,7]$.

A graph $G$ is a geodetic graph [10] if any two vertices of $G$ are joined by a unique shortest path and $G$ is weakly geodetic if for every pair of vertices of distance two, there is a unique common neighbour [7]. A graph $G$ is weakly geodetic if and only if $b(G) \geq 5[6,7]$. It is known that block graphs $\subseteq$ geodetic graphs $\subseteq$ weakly geodetic graphs [1].
$P_{4}$-free graphs are called cographs [3]. The domination number of cographs is at most two [12].

It is well known that $K_{1,3}$ and $K_{3}$ are the only non isomorphic graphs with isomorphic line graphs. Even though $L(G) \subseteq E_{4}(G)$, it is proved in this paper that there exist infinitely many pairs of non isomorphic graphs with isomorphic edge $C_{4}$ graphs. We study relations between $\gamma(G)$ and $\gamma\left(E_{4}(G)\right.$ ), $\operatorname{diam}(G)$ and $\operatorname{diam}\left(E_{4}(G)\right)$, and $\operatorname{rad}(G)$ and $\operatorname{rad}\left(E_{4}(G)\right)$. We prove that for
any graph $G$ without isolated vertices, it is possible to construct a super graph $H$ such that $C(H)=G$ and $C\left(E_{4}(H)\right)=E_{4}(G)$. We also obtain forbidden subgraph characterizations for $E_{4}(G)$ being threshold graph, block graph, geodetic graph and weakly geodetic graph.

## 2. Some Properties of $E_{4}(G)$

Theorem 1. There exist infinitely many pairs of non isomorphic graphs whose edge $C_{4}$ graphs are isomorphic.

Proof. Let $G=K_{1, n}$. If $n=2 k-1$, then take $H=K_{2} \vee(k-1) K_{1}$ and if $n=2 k$, then take $H=2 K_{1} \vee k K_{1}$. Clearly $G$ and $H$ are non isomorphic graphs. But $E_{4}(G)=E_{4}(H)=K_{n}$.

Theorem 2. For a connected graph $G$, $\operatorname{diam}(G)-1 \leq \operatorname{diam}\left(E_{4}(G)\right) \leq$ $\operatorname{diam}(G)+1$ and $\operatorname{rad}(G)-1 \leq \operatorname{rad}\left(E_{4}(G)\right) \leq \operatorname{rad}(G)+1$.

Proof. By the definition of $E_{4}(G)$ and $L(G), \operatorname{diam}\left(E_{4}(G)\right) \leq \operatorname{diam}(L(G))$ and $\operatorname{rad}\left(E_{4}(G)\right) \leq \operatorname{rad}(L(G))$. But, $\operatorname{diam}(L(G)) \leq \operatorname{diam}(G)+1$ and $\operatorname{rad}(L(G)) \leq \operatorname{rad}(G)+1$. Thus $\operatorname{diam}\left(E_{4}(G)\right) \leq \operatorname{diam}(G)+1$ and $\operatorname{rad}\left(E_{4}(G)\right)$ $\leq \operatorname{rad}(G)+1$.

Next let $\operatorname{diam}(G)=k$. We want to prove that $\operatorname{diam}\left(E_{4}(G)\right) \geq k-1$. On the contrary, assume that $\operatorname{diam}\left(E_{4}(G)\right)<k-1$. Let $u$ and $v$ be any two vertices in $G$ and let $u-u^{\prime}, v-v^{\prime}$ be any two edges incident with $u$ and $v$ respectively. But $d_{E_{4}(G)}\left(u u^{\prime}, v v^{\prime}\right)<k-1$. So $d_{G}(u, v) \leq d_{E_{4}(G)}\left(u u^{\prime}, v v^{\prime}\right)+$ $1<k$, which is a contradiction to the fact that $\operatorname{diam}(G)=k$.

Finally, let $\operatorname{rad}(G)=k$. It is required to prove that $\operatorname{rad}\left(E_{4}(G) \geq k-1\right.$. On the contrary, suppose that $\operatorname{rad}\left(E_{4}(G)\right)<k-1$. Then there exists a vertex $u u^{\prime}$ in $E_{4}(G)$ such that $e\left(u u^{\prime}\right)<k-1$. Consider the vertex $u$ in $G$. Let $v$ be any vertex in $G$ and $v v^{\prime}$ be any edge incident with $v$. Then $d_{G}(u, v) \leq d_{E_{4}(G)}\left(u u^{\prime}, v v^{\prime}\right)+1<k$, and hence $e(u)<k$, which is a contradiction to the fact that $\operatorname{rad}(G)=k$.

Note 1. The bounds in Theorem 2 are strict.
If $G$ is a bow, then $\operatorname{diam}(G)=2, \operatorname{diam}\left(E_{4}(G)\right)=3, \operatorname{rad}(G)=1$ and $\operatorname{rad}\left(E_{4}(G)\right)=2$.
If $G$ is $C_{4}$, then $\operatorname{diam}(G)=2, \operatorname{diam}\left(E_{4}(G)\right)=1, \operatorname{rad}(G)=2$ and $\operatorname{rad}\left(E_{4}(G)\right)=1$.

Theorem 3. For any graph $G$ without isolated vertices, there exists a super graph $H$ such that $C(H)=G$ and $C\left(E_{4}(H)\right)=E_{4}(G)$.

Proof. Consider $G \vee 2 K_{2}$. Let the $K_{2}$ 's be $a-a^{\prime}$ and $b-b^{\prime}$. Attach $a^{\prime \prime}-a^{\prime \prime \prime}$ to $a-a^{\prime}$ such that $a$ is adjacent to $a^{\prime \prime \prime}$ and $a^{\prime}$ is adjacent to $a^{\prime \prime}$. Similarly attach $b^{\prime \prime}-b^{\prime \prime \prime}$ to $b-b^{\prime}$ such that $b$ is adjacent to $b^{\prime \prime \prime}$ and $b^{\prime}$ is adjacent to $b^{\prime \prime}$. The graph so obtained is $H$.

Claim 1. $C(H)=G$.
We prove that among the vertices in $H$, those vertices which are in $G$ also have minimum eccentricity.
$e(u)=2$, if $u \in V(G)$.
$=3$, if $u \in\left\{a, a^{\prime}, b, b^{\prime}\right\}$.
$=4$, if $u \in\left\{a^{\prime \prime}, a^{\prime \prime \prime}, b^{\prime \prime}, b^{\prime \prime \prime}\right\}$.
Hence Claim 1 is proved.
Let $u_{1}, u_{2}, \ldots, u_{m}$ be the vertices in $G$. Consider $\left.E_{4}(H)\right)$. Let $x$ be any vertex in $E_{4}(H)$.

Claim 2. $C\left(E_{4}(H)\right)=E_{4}(G)$.
$e(x)=2$, if $x \in\left\{u_{i} u_{j} / u_{i}\right.$ is adjacent to $u_{j}$ in $G, i, j=1,2, \ldots, m, i \neq j$.
$=3$, if $x \in\left\{a a^{\prime}, b b^{\prime}, a u_{i}, a^{\prime} u_{i}, b u_{i}, b^{\prime} u_{i}\right\}, i=1,2, \ldots, m$.
$=4$, if $x \in\left\{a^{\prime} a^{\prime \prime}, a a^{\prime \prime \prime}, b^{\prime} b^{\prime \prime}, b b^{\prime \prime \prime}, a^{\prime \prime} a^{\prime \prime \prime}, b^{\prime \prime} b^{\prime \prime \prime}\right\}$.
Illustration: Let $G=P_{3}$. Then $H$ :

## 3. A Bound on the Domination Number of $E_{4}(G)$

Theorem 4. For a connected graph $G, \gamma(G) \leq 2 \gamma\left(E_{4}(G)\right)$. Given any two integers $a$ and $b$ such that $a \leq 2 b$, there exists a graph $G$ such that $\gamma(G)=a$ and $\gamma\left(E_{4}(G)\right)=b$.

Proof. Let $\gamma\left(E_{4}(G)\right)=b$ and let $\left\{e_{1}=v_{1} v_{1}^{\prime}, e_{2}=v_{2} v_{2}^{\prime}, \ldots, e_{b}=v_{b} v_{b}^{\prime}\right\}$ dominate $E_{4}(G)$. Consider $S=\left\{v_{1}, v_{1}^{\prime}, v_{2}, v_{2}^{\prime}, \ldots, v_{b}, v_{b}^{\prime}\right\}$. Then $S \subseteq V(G)$. Let $w$ be any vertex in $V(G)$. Since $G$ is a connected graph, $w$ must be the end vertex of an edge $w-w^{\prime}$. But the vertex $w w^{\prime}$ in $E_{4}(G)$ is dominated and hence is adjacent to at least one of the $b$ vertices. Let $e_{i}$ be adjacent to $w w^{\prime}$ in $E_{4}(G)$. Then in $G$, either $e_{i}$ is incident with $w-w^{\prime}$ or $e_{i}$ and $w-w^{\prime}$ are the opposite edges of some $C_{4}$. In both the cases, $w$ is dominated by $v_{i}$ or $v_{i}^{\prime}$. Thus $S$ is a dominating set of $G$ and hence $\gamma(G) \leq 2 \gamma\left(E_{4}(G)\right)$.

## 4. Some Theorems on Graph Classes

Theorem 5 [9]. For a connected graph $G, E_{4}(G)$ is complete if and only if $G$ is a complete multipartite graph.

Theorem 6. Let $G$ be a connected graph such that $E_{4}(G)$ is a threshold graph. Then $\gamma(G) \leq 2$.

Proof. We know that $E_{4}(G)$ is a threshold graph if and only if $\operatorname{dilw}\left(E_{4}(G)\right)$ $=1$. Also $\operatorname{dilw}\left(E_{4}(G)\right) \geq \gamma\left(E_{4}(G)\right)$. Then the theorem follows from Theorem 4.

The graph obtained from $K_{4}$ by attaching two pendant vertices to the same vertex of $K_{4}$ is denoted by $H$.

Theorem 7. If $G$ is a threshold graph then $E_{4}(G)$ is a threshold graph if and only if $G$ is $\{$ moth, $H\}$-free.

Proof. Let $G$ be a threshold graph. If $G$ contains a moth graph or $H$ as an induced sub graph, then $E_{4}(G)$ contains a $2 K_{2}$ and hence it cannot be threshold.

Conversely, suppose that $G$ is a $\{\operatorname{moth}, H\}$-free threshold graph. Since $G$ is threshold, $\operatorname{dilw}(G)=1$ and hence $\gamma(G)=1$. So $G$ must have a universal vertex $u$.

If at most two vertices in $N(u)$ are of degree greater than one, then $E_{4}(G)$ cannot contain an induced $2 K_{2}, C_{4}$ or $P_{4}$.

Now let $k, k \geq 3$ vertices in $N(u)$ are of degree greater than one.
Claim: There exist three vertices $u_{1}, u_{2}, u_{3}$ such that the vertex $u_{2}$ is adjacent to $u_{1}$ and $u_{3}$.

If $k=3$, this claim holds true. If $k>3$, let $u_{1}, u_{2}, u_{3}$ and $u_{4}$ be four vertices of degree greater than one in $N(u)$ such that $u_{1}$ is adjacent to $u_{2}$ and $u_{3}$ is adjacent to $u_{4}$. Since $G$ is threshold, it can not contain an induced $2 K_{2}$ and hence $u_{3}$ or $u_{4}$ must be adjacent to $u_{1}$ or $u_{2}$. Let $u_{3}$ be adjacent to $u_{1}$. Then $u_{2}, u_{1}, u_{3}, u_{4}$ forms an induced $P_{4}$ which is not possible since $G$ is threshold. In this case, if $u_{4}$ is adjacent to $u_{2}$, then $G$ contains an induced $C_{4}$ which is again not possible. Hence the claim.

Further if $u_{1}$ and $u_{3}$ are adjacent, the vertex $u$ can have at most one more neighbour since $G$ is $H$-free. In this case also $E_{4}(G)$ is threshold since it is $\left\{2 K_{2}, C_{4}, P_{4}\right\}$-free. On the other hand if $u_{1}$ and $u_{3}$ are not adjacent,
then since $G$ is moth-free, the vertex $u$ can have at most one more neighbour. In this case also $E_{4}(G)$ is threshold.

Remark. Let $G$ be a connected graph such that $E_{4}(G)$ is a cograph. Then $\gamma(G) \leq 4$, which follows from Theorem 4 and the fact that the domination number of cographs is at most two.

Theorem 8. Let $G$ be a connected graph. Then

1. $E_{4}(G)$ is a weakly geodetic graph if and only if $G$ is $\{$ paw, 4-pan\}-free.
2. $E_{4}(G)$ is a geodetic graph if and only if $G$ is $\left\{C_{2 n}: n>2\right\} \cup\{4$ pan $\} \cup\{2 n-1: n>1\}$-free.
3. $E_{4}(G)$ is a block graph if and only if $G$ is $\{$ paw, 4-pan $\} \cup\left\{C_{n}: n \geq 5\right\}$ free.

Proof. 1. If $G$ contains a paw in which $C_{3}=\left(u_{1}, u_{2}, u_{3}\right)$ and $a$ is a pendant vertex attached to $u_{1}$, then in $E_{4}(G), d\left(a u_{1}, u_{2} u_{3}\right)=2$, but they have two common neighbours $u_{1} u_{2}$ and $u_{1} u_{3}$. Similarly if $G$ contains a 4-pan in which $C_{4}=\left(u_{1}, u_{2}, u_{3}, u_{4}\right)$ and $a$ is a pendant vertex attached to $u_{1}$, then in $E_{4}(G), d\left(a u_{1}, u_{3} u_{4}\right)=2$, but they have two neighbours $u_{1} u_{2}$ and $u_{1} u_{4}$.

Conversely, suppose that $G$ is a \{paw, 4-pan\}-free graph. If $G$ is an acyclic graph, there exists a unique shortest path joining any two vertices in $E_{4}(G)$. Thus $E_{4}(G)$ is weakly geodetic.

Next suppose that $G$ contains cycles.
If $g(G)=3$ then $G$ contains a $C_{3}=\left(u_{1}, u_{2}, u_{3}\right)$.
Claim. $G$ is a cograph.
Suppose that $G$ contains an induced $P_{4}=\left(v_{1}, v_{2}, v_{3}, v_{4}\right)$. Let $u_{1} \neq v_{1}$. Consider a shortest path $\left(u_{1}, a_{1}, a_{2}, \ldots, a_{k}, v_{1}\right)$ joining $u_{1}$ and $v_{1}$. Since $G$ is paw free $a_{1}$ must be adjacent to at least one more $u_{i}, i=2,3$. Proceeding like this, $v_{1}$ and then $v_{2}$ must be adjacent to at least two $u_{i}$ 's. This implies that $v_{1}$ and $v_{2}$ must have a common neighbour among the $u_{i} s$. Let it be $u_{1}$. Then $\left(v_{1}, u_{1}, v_{2}\right)$ form a $C_{3}$. Since $G$ is paw-free, $v_{3}$ must be adjacent to at least one of $v_{1}$ and $u_{1}$. But, since $\left(v_{1}, v_{2}, v_{3}, v_{4}\right)$ is an induced $P_{4}, v_{3}$ must be adjacent to $u_{1}$. Then $\left(v_{1}, u_{1}, v_{3}\right)$ will form a $C_{3}$ in $G$. Again since $G$ is paw-free, $v_{4}$ must be adjacent to $u_{1}$. Now, consider $\left(v_{1}, u_{1}, v_{2}\right)$ with the edge $u_{1}-v_{4}$. Since $G$ is paw-free, $v_{4}$ must be adjacent to $v_{1}$ or $v_{2}$, which is a contradiction.

But a paw-free cograph is a complete multipartite graph and hence by Theorem $5, E_{4}(G)$ is complete and thus weakly geodetic.

If $g(G)=4$, then $G$ contains a $C_{4}=\left(u_{1}, u_{2}, u_{3}, u_{4}\right)$. If $G=C_{4}$, then $E_{4}(G)=K_{4}$. If there exists a vertex $v_{1}$ in $G$ which is adjacent to $u_{1}, v_{1}$ must be adjacent to $u_{3}$ also since $G$ is 4 -pan-free. Similarly if there exists a vertex $v_{2}$ which is adjacent to $u_{2}, v_{2}$ must be adjacent to $u_{4}$. If there exists a vertex $v_{1}^{\prime}$ which is adjacent to $v_{1}$, it must be adjacent to both $u_{2}$ and $u_{4}$. Hence $G$ is a complete bipartite graph. Since $g(G)=4, G$ is paw-free. Again by Theorem $5, E_{4}(G)$ is complete, and hence $G$ is a weakly geodetic graph.

Finally, Let $g(G)=k, k>4$. Let $\left(u_{1}, u_{2}, u_{3}, \ldots, u_{k}\right)$ be a $C_{k}$ in $G$. Then $E_{4}(G)$ also contains a $C_{k}$. This $C_{k}$ is not a part of any clique in $E_{4}(G)$ and hence $b\left(E_{4}(G)\right) \leq k$. Since $G$ does not contain any $C_{4}$, two vertices in $E_{4}(G)$ are adjacent if and only if the corresponding edges in $G$ are adjacent. Thus $E_{4}(G)$ cannot contain a $b$-cycle of length less than $k$ and so $b\left(E_{4}(G)\right)=k$ where $k>4$. We know that a graph $G$ is weakly geodetic if and only if $b(G) \geq 5$. Thus $E_{4}(G)$ is a weakly geodetic graph.
2. Let $E_{4}(G)$ be a geodetic graph. If $G$ contains a 4-pan, there exists more than one shortest path joining two vertices in $E_{4}(G)$ as proved earlier. If $G$ contains a $C_{2 n}=\left(u_{1}, u_{2}, \ldots, u_{2 n}\right)$, then $u_{1} u_{2}$ and $u_{n+1} u_{n+2}$ in $E_{4}(G)$ are connected by more than one shortest path and hence $E_{4}(G)$ is not geodetic. If $G$ contains a $(2 n-1)$-pan in which $C_{2 n-1}=\left(u_{1}, u_{2}, \ldots, u_{2 n-1}\right)$ and $a$ is a pendant vertex attached to $u_{1}$, then $a u_{1}$ and $u_{n} u_{n+1}$ in $E_{4}(G)$ are connected by more than one shortest path and hence $E_{4}(G)$ is not geodetic.

Conversely, assume that $G$ is $\left\{4\right.$-pan, $C_{2 n},(2 n-1)$-pan $\}$-free. If $G$ is an acyclic graph there exists a unique shortest path joining any two vertices in $E_{4}(G)$ and hence is geodetic. So consider the graphs $G$ containing cycles.

Let $g(G)=3$. Since $G$ is paw-free, $E_{4}(G)$ is complete and hence is geodetic. If $g(G)=4, E_{4}(G)$ is complete since $G$ is 4-pan-free and thus geodetic. If $g(G)=2 n-1, n>2$, then $G$ contains a $C_{2 n-1}=\left(u_{1}, u_{2}, \ldots, u_{2 n-1}\right)$. If $G=C_{2 n-1}$, then $E_{4}(G)=C_{2 n-1}$ and hence geodetic. If $a$ is a vertex attached to $u_{1}$, since $G$ is $(2 n-1)$-pan-free, $a$ must be adjacent to at least one more $u_{i}$. But this is impossible since $g(G)=2 n-1$. Since $G$ is $C_{2 n}$-free, $g(G) \neq 2 n, n>2$. Hence in all the cases, it follows that $E_{4}(G)$ is geodetic.
3. Let $E_{4}(G)$ be a block graph. If $G$ contains a paw in which $C_{3}=$ $u_{1}, u_{2}, u_{3}$ and $a$ is the pendant vertex adjacent to $u_{1}$, then $E_{4}(G)$ contains a $C_{4}=\left(a u_{1}, u_{1} u_{2}, u_{2} u_{3}, u_{3} u_{1}\right)$ which is not a part of any clique. Thus $b\left(E_{4}(G)\right) \leq 4$. Similarly if $G$ contains a 4-pan, in which $C_{4}=$
$\left(u_{1}, u_{2}, u_{3}, u_{4}\right\}$ and $a$ is a pendant vertex adjacent to $u_{1}$, then $E_{4}(G)$ contains a $C_{4}=\left(a u_{1}, u_{1} u_{2}, u_{3} u_{4}, u_{4} u_{1}\right)$ which is not a part of any clique and hence $b\left(E_{4}(G)\right) \leq 4$. If $G$ contains a $C_{n}, n>4$, then $E_{4}(G)$ also contains a $C_{n}, n>4$. This $C_{n}$ forms a $b$-cycle and hence $b\left(E_{4}(G)\right) \leq n$ and hence $E_{4}(G)$ is not a block graph.

Conversely, suppose that $G$ is \{paw, 4-pan $\} \cup\left\{C_{n}: n>4\right\}$-free. If $G$ is an acyclic graph, then $E_{4}(G)$ cannot contain a b-cycle and hence is a block graph. Now, consider the graphs $G$ containing cycles. Since $G$ is $\left\{C_{n}: n \geq 5\right\}$-free, $g(G)=3$ or 4 . But since $G$ is \{paw, 4-pan\}-free, $E_{4}(G)$ is complete as proved earlier and thus is a block graph.
