#### Abstract

In this paper, we consider the least integer $d$ such that every longest cycle of a $k$-connected graph of order $n$ (and of independent number $\alpha$ ) contains all vertices of degree at least $d$. Keywords: longest cycle, large degree vertices, order, connectivity, independent number.

2010 Mathematics Subject Classification: 05C38.

## 1. Introduction

### 1.1. Basic notation and terminology

All graphs considered here are simple and finite. For standard graph-theoretic terminology not explained in this paper, we refer the reader to [2]. Let $G$ be a graph. For a vertex $v \in V(G)$ and a subgraph $H$ of $G$, we use $N_{H}(v)$ and $d_{H}(v)$ to denote the set and the number of neighbors of $v$ in $H$, respectively. We call $N_{H}(v)$ the neighborhood of $v$ in $H$ and $d_{H}(v)$ the degree of $v$ in $H$. We use $d_{H}(u, v)$ to denote the distance between two vertices $u, v \in V(H)$ in $H$. For two subgraphs $H$ and $L$ of a graph $G$, we set $N_{L}(H)=\bigcup_{v \in V(H)} N_{L}(v)$. When no confusion occurs, we will denote $N_{G}(v)$ and $d_{G}(v)$ by $N(v)$ and $d(v)$, respectively. We set $N[x]=N(x) \cup\{x\}$.

Throughout this paper, we denote the order, the connectivity and the independent number of a graph $G$, by $n(G), \kappa(G)$ and $\alpha(G)$, respectively.

### 1.2. Motivation and main results of this paper

By the definition every Hamilton cycle of a graph passes through every vertex of the graph. Thus, in non-Hamiltonian graphs, a (longest) cycle through some special vertices should be also interesting for the same topic. There are many results on the problem whether a graph has a (longest) cycle through some special vertices, for example, any given vertex set [8]; large degree vertices, see [1, 7, 9]. Unlike most research of the existence of some (longest) cycle passing through special vertices in the literature, we put our attention to the problem to determine the least integer $d$ such that every longest cycle of a graph passes all vertices of degree at least $d$, using some additional conditions of order, of connectivity or of independence number.

The following known result gave a partly answer for the above problem.
Theorem 1 (Li and Zhang [6]). Let $G$ be a 2 -connected graph of order $n \geq 8$. Then every longest cycle of $G$ contains all vertices of degree at least $n-4$.

We firstly extend Theorem 1 to $k$-connected graphs for any $k \geq 2$ and shall give a complete answer for the above problem by using the order of a graph and its connectivity.

Theorem 2. Let $G$ be a graph of connectivity $\kappa(G) \geq k \geq 2$ and of order $n \geq 6 k-4$. Then every longest cycle of $G$ contains all vertices of degree at least $n-3 k+2$.

The bound on the degree in Theorem 2 is sharp. We construct a graph as follows. Let $R=2 K_{2} \cup(k-2) P_{3}, S=k K_{1}$ and $T=(n-4 k+1) K_{1}$ are vertex-disjoint. Let $R^{\prime}$ be the subset of $V(R)$ each vertex of which is either
a vertex of a $K_{2}$ or a center of a $P_{3}$ in $R$, and let $s^{\prime}$ be a fixed vertex of $S$ and $x$ a vertex not in $R \cup S \cup T$. Let $L(k, n)$ be the graph with $V(L(k, n))=$ $\{x\} \cup V(R) \cup V(S) \cup V(T)$, and $E(L(k, n))=E(R) \cup\left\{r^{\prime} s^{\prime}, r s, s^{\prime} x, s x, s t, x t\right.$ : $\left.r^{\prime} \in R^{\prime}, r \in V(R), s \in V(S) \backslash\left\{s^{\prime}\right\}, t \in V(T)\right\}$. One can check that $L(k, n)$ is $k$ connected and the degree of $x$ is $n-3 k+1$, but there is a longest cycle (in the subgraph induced by $V(R) \cup V(S))$ excluding $x$.

Figure 1. Graph $L(4,21)$.
The bound $n \geq 6 k-4$ is also sharp. This can be seen from the complete bipartite graph $K_{3 k-3,3 k-2}$ of order $6 k-5$. However, the longest cycles of $K_{3 k-3,3 k-2}$ exclude some vertices of degree $3 k-3=n-3 k+2$.

Now we define $\varphi(k, n)$ to be the least integer such that every longest cycle of a $k$-connected graph $G$ of order $n$ contains all vertices of degree at least $\varphi(k, n)$ in $G$.

To avoid the discussions of the petty cases, we put our considerations on 2 -connected graphs, i.e., we always assume that $k \geq 2$. Note that if $n \leq k$, then there are no $k$-connected graphs of order $n$. Hence $\varphi(k, n)$ will be meaningless. Is $\varphi(k, n)$ well-defined for all pairs ( $k, n$ ) with $n \geq k+1$ ? No. Under the condition that it holds "every $k$-connected graph on $n$ vertices is Hamiltonian" (e.g., $n=k+1$ ), $\varphi(k, n)$ does not exist (or we may say $\varphi(k, n)=-\infty$ ). So we should take the pair $(k, n)$ such that there exist some $k$-connected graphs of order $n$ which are not Hamiltonian. This implies that $n \geq 2 k+1$ from the well-known Dirac's theorem [4]. On the other hand, there indeed exist such graphs when $n \geq 2 k+1$ (for example, complete bipartite graphs $K_{k, n-k}$ ). So $\varphi(k, n)$ is well-defined if and only if $n \geq 2 k+1$.

From Theorem 2 and the construction of $L(k, n)$, we have

$$
\varphi(k, n)=n-3 k+2, \text { for } n \geq 6 k-4 .
$$

How about the cases when $2 k+1 \leq n \leq 6 k-5$ ? First we construct a graph as follows: if $n$ is odd, then let $L(k, n)=K_{(n-1) / 2,(n+1) / 2}$; if $n$ is even, then let $L(k, n)=K_{n / 2-1, n / 2+1}$. Note that every longest cycle of $L(k, n)$ excludes some vertices of degree $\lceil n / 2\rceil-1$. This shows that $\varphi(k, n) \geq\lceil n / 2\rceil$. On the other hand, we have the following result (one may compare it with the results in [1] and [9] where they replaced "every cycle" with "there exists some cycle" under the condition that " $G$ is 2 -connected").
Theorem 3. Let $G$ be a $k$-connected graph on $n \leq 6 k-5$ vertices. Then every longest cycle of $G$ contains all vertices of degree at least $\lceil n / 2\rceil$.

Instead of Theorems 2 and 3, we shall prove the following theorem in Section 3.

Theorem 4. Let $G$ be a graph of connectivity $\kappa(G) \geq k \geq 2$ and of order $n \geq 2 k+1$. Then every longest cycle of $G$ contains all vertices of degree at least

$$
d=\max \left\{\left\lceil\frac{n}{2}\right\rceil, n-3 k+2\right\} .
$$

Now we have a complete formula

$$
\varphi(k, n)=\max \left\{\left\lceil\frac{n}{2}\right\rceil, n-3 k+2\right\}, \text { for all } n \geq 2 k+1
$$

In the following we consider the same problem by using an additional condition of independent number. We use $\varphi(k, \alpha, n)$ to denote the least integer such that for every $k$-connected graph $G$ of order $n$ and of independent number $\alpha$, every longest cycle of $G$ contains all vertices of degree at least $\varphi(k, \alpha, n)$. As the analysis above, we should take the triple ( $k, \alpha, n$ ) such that there exists a $k$-connected graph of order $n$ and independent number $\alpha$ that is not Hamiltonian. This requires $\alpha \geq k+1$ from Chvátal-Erdös's theorem [3]; and $\alpha \leq n-k$, since every $k$ connected graph of order $n$ has independent number at most $n-k$ (note that an independent set excludes the $k$ neighbors of some vertex). On the other hand, for triple $(k, \alpha, n)$ with $k+1 \leq \alpha \leq n-k$, the graph $k K_{1} \vee\left((\alpha-1) K_{1} \cup K_{n-k-\alpha+1}\right)$ is a $k$-connected graph of order $n$ and independent number $\alpha$ that is not Hamiltonian. Thus $\varphi(k, \alpha, n)$ is well-defined if and only if $k+1 \leq \alpha \leq n-k$.

By the definition of $\varphi(k, n)$, we can see that

$$
\varphi(k, n)=\max \{\varphi(k, \alpha, n): k+1 \leq \alpha \leq n-k\}, \text { for all } n \geq 2 k+1
$$

Using a result in [10], we can prove the following result.
Theorem 5. Let $G$ be a $k$-connected graph of order $n$ and of independent number $\alpha$. Then every longest cycle of $G$ contains all vertices of degree more than

$$
d_{0}=\frac{(\alpha-k) n-k \alpha+k^{2}+\alpha^{2}-2 \alpha}{\alpha} .
$$

Taking $\alpha=k+1$ in the above theorem, we can obtain the following correspondence.

Theorem 6. Let $G$ be a graph of connectivity $\kappa(G) \geq k \geq 2$, of order $n \geq 2 k+1$ and of independent number $k+1$. Then every longest cycle of $G$ contains all vertices of degree at least

$$
d=\left\lfloor\frac{n+1}{k+1}\right\rfloor+k-1 .
$$

The bound on $d$ in Theorem 6 is sharp. We construct a graph $L(k, k+1, n)$ by joining each vertex of $R=k K_{1}$ to all vertices of $S=r K_{q+1} \cup(k+1-r) K_{q}$, where

$$
n-k=q(k+1)+r, \quad 0 \leq r \leq k .
$$

Note that $L(k, k+1, n)$ has a longest cycle excluding some vertices of degree

$$
q+k-1=\left\lfloor\frac{n-k}{k+1}\right\rfloor+k-1=\left\lfloor\frac{n+1}{k+1}\right\rfloor+k-2 .
$$

By Theorem 6, the above equality implies that

$$
\varphi(k, k+1, n)=\left\lfloor\frac{n+1}{k+1}\right\rfloor+k-1, \text { for all } n \geq 2 k+1
$$

Thus, in the following we will assume that $\alpha \geq k+2$. For the case $k=2$, we have the following result.

Theorem 7. Let $G$ be a 2-connected graph of order $n \geq 8$ and independent number $\alpha \geq 4$. Then every longest cycle of $G$ contains all vertices of degree at least

$$
d=\left\lfloor\frac{n-5}{\alpha}\right\rfloor(\alpha-2)+\max \left\{3, n-4-\left\lfloor\frac{n-5}{\alpha}\right\rfloor \alpha\right\}
$$

i.e.,

$$
d= \begin{cases}q(\alpha-2)+3, & 0 \leq r \leq 2, \\ q(\alpha-2)+r+1, & 3 \leq r<\alpha,\end{cases}
$$

where

$$
n-5=q \alpha+r, 0 \leq r<\alpha .
$$

The bound on $d$ in Theorem 7 is sharp when $q \geq 1$ (i.e., when $n \geq \alpha+5$ ). We construct extremal graphs as follows. If $0 \leq r \leq 2$, then let $R=r K_{q+2} \cup$ $(2-r) K_{q+1}$ and $T=(\alpha-2) K_{q}$; if $3 \leq r<\alpha$, then let $R=2 K_{q+2}$ and $T=$ $(r-2) K_{q+1} \cup(\alpha-r) K_{q}$. Let $s^{\prime}, s, x$ be three vertices not in $R \cup T$. Let $L(2, \alpha, n)$
be a graph with the vertex set $V(L(2, \alpha, n))=\left\{s^{\prime}, s, x\right\} \cup V(R) \cup V(T)$ and the edge set

$$
E(L(2, \alpha, n))=E(R) \cup E(T) \cup\left\{s^{\prime} r, s r, s^{\prime} x, s x, s t, x t: r \in V(R), t \in V(T)\right\}
$$

One can check that $L(2, \alpha, n)$ is a 2 -connected graph of order $n$ and of independent number $\alpha$, and $x$ has degree $d-1$. But there is a longest cycle of $G$ excluding $x$. By Theorem 7, this implies that for $n \geq \alpha+5$,

$$
\varphi(2, \alpha, n)= \begin{cases}q(\alpha-2)+3, & 0 \leq r \leq 2 \\ q(\alpha-2)+r+1, & 3 \leq r<\alpha\end{cases}
$$

where

$$
n-5=q \alpha+r, 0 \leq r<\alpha
$$

For the case $q=0$, the above construction does not give the exact value of $\varphi(2, \alpha, n)$, since the independent number of the constructed graph is less than $\alpha$. What is its exact values for this case?

Note that $n \leq \alpha+4$ in this case. Also note that in our assumption $n \geq \alpha+2$. We have three cases: $n=\alpha+2, n=\alpha+3$ and $n=\alpha+4$.

Theorem 8. Let $G$ be a 2-connected graph of independent number $\alpha \geq 4$ and of order $n$ such that $\alpha+2 \leq n \leq \alpha+4$. Then every longest cycle of $G$ contains all vertices of degree at least

$$
d= \begin{cases}n-\alpha+1, & n-\alpha=2,3 \\ \alpha, & n-\alpha=4\end{cases}
$$

Now we will show the sharpness of the bound in Theorem 8. For the case $n=\alpha+2$, consider the graph $L(2, \alpha, \alpha+2)=K_{2, \alpha}$. Note that every longest cycle of $L(2, \alpha, \alpha+2)$ excludes some vertices of degree 2 .

For the case $n=\alpha+3$, consider the graph $L(2, \alpha, \alpha+3)=K_{3, \alpha}$. Note that every longest cycle of $L(2, \alpha, \alpha+3)$ excludes some vertices of degree 3 .

Now we consider the case $n=\alpha+4$. We construct the graph $L(2, \alpha, \alpha+4)$ by combining a cycle $C_{6}$ and a star $K_{1, \alpha-3}$ in such a way: choosing two vertices $u, v$ in $C_{6}$ with distance 3 , joining the center $x$ of the star to $u$ and $v$, and joining all the end-vertices of the star to $v$. Note that one longest cycle of $L(2, \alpha, \alpha+4)$ excludes $x$ of degree $\alpha-1$.

Therefore, we give formulas for $\alpha \geq 4$,

$$
\begin{aligned}
& \varphi(2, \alpha, \alpha+2)=3 \\
& \varphi(2, \alpha, \alpha+3)=4 \\
& \varphi(2, \alpha, \alpha+4)=\alpha
\end{aligned}
$$

The bound of $d_{0}$ in Theorem 5 seems not sharp for $\alpha \geq k+2$ (at least it is not sharp when $k=2$ ). We propose the following conjecture.

Figure 2. Graph $L(2, \alpha, \alpha+4)$.
Conjecture 9. Let $G$ be a $k$-connected graph, $k \geq 3$, of independent number $\alpha \geq k+2$ and of order $n \geq \max \{2 \alpha+1, \alpha+3 k+1\}$. Then every longest cycle of $G$ contains all vertices of degree at least

$$
d= \begin{cases}q(\alpha-k)+k+1, & 0 \leq r \leq k, \\ q(\alpha-k)+k+2, & k+1 \leq r \leq 2 k+1 \\ q(\alpha-k)+r-k+1, & 2 k+2 \leq r<\alpha+k\end{cases}
$$

where

$$
n-2 k-1=q(\alpha+k)+r, 0 \leq r<\alpha+k .
$$

We remark that if the conjecture is true, then the bound on $d$ is sharp. We construct a graph as follows. If $0 \leq r \leq k$, then let $R=r K_{2 q+2} \cup(k-r) K_{2 q+1}$ and $T=(\alpha-k) K_{q}$; if $k+1 \leq r \leq 2 k+1$, then let $R=(r-k-1) K_{2 q+3} \cup(2 k+1-r) K_{2 q+2}$ and $T=K_{q+1} \cup(\alpha-k-1) K_{q}$; if $2 k+2 \leq r<\alpha+k$, then let $R=k K_{2 q+3}$ and $T=(r-2 k) K_{q+1} \cup(\alpha+k-r) K_{q}$, and let $S=k K_{1}$. Let $x$ be a vertex not in $R \cup S \cup T$. Let $L(k, \alpha, n)$ be a graph with $V(L(k, \alpha, n))=\{x\} \cup V(R) \cup V(S) \cup V(T)$ and

$$
E(L(k, \alpha, n))=E(R) \cup E(T) \cup\{s r, s x, s t, x t: r \in V(R), s \in V(S), t \in V(T)\} .
$$

One can check that $L(k, \alpha, n)$ is a 2-connected graph of order $n$ and of independent number $\alpha$, and $x$ has degree $d-1$. But there is a longest cycle of $G$ excluding $x$.

## 2. Preliminaries

Let $G$ be a graph and $x, y \in V(G)$. An $x$-path is a path with $x$ as one of its end vertices; an $(x, y)$-path is one connecting $x$ and $y$. If $Y$ is a subset of $V(G)$, then an $(x, Y)$-path is one connecting $x$ and a vertex in $Y$ with all internal vertices in
$V(G) \backslash Y$; a $Y$-path is one connecting two vertices in $Y$ with all internal vertices in $V(G) \backslash Y$. For a subgraph $H$ of $G$, we use the notations $(x, H)$-path and $H$ path instead of $(x, V(H))$-path and $V(H)$-path, respectively. It is convenient to denote a path $P$ with end-vertices $x, y$ by $P(x, y)$.

For a cycle $C$ with a given orientation and a vertex $x$ on $C$, we use $x^{+}$to denote the successor, and $x^{-}$the predecessor of $x$ on $C$. In the following, we always assume that $C$ has an orientation, $\vec{C}$. For two vertices $x, y$ on $C, \vec{C}[x, y]$ or $\overleftarrow{C}[y, x]$ denotes the path from $x$ to $y$ along $\vec{C}$. Similarly, if $x, y$ are two vertices in a path $P, P[x, y]$ denotes the subpath of $P$ between $x$ and $y$. For an arbitrary path $P$ or cycle $C$, we use $l(P)$ or $l(C)$ to denote the length (the number of edges) of it.

We first give some lemmas on longest cycles of graphs.
Lemma 10. Let $C$ be a longest cycle of a graph $G$, and $P=P(u, v)$ be a $C$-path. Then $l(\vec{C}[u, v]) \geq l(P)$.
Proof. Otherwise, $\vec{C}[v, u] u P v$ is a cycle longer than $C$, a contradiction.
Lemma 10 can be extended to the following.
Lemma 11. Let $C$ be a longest cycle of a graph $G, H$ be a component of $G-C$ and $P=P(u, v)$ be a $C$-path of length at least 2 with all internal vertices in $H$. Then

$$
l(\vec{C}[u, v]) \geq l(P)+2\left|N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)\right|
$$

Proof. We use induction on $\left|N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)\right|$. If $N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)$ $=\emptyset$, then we are done by Lemma 10. Now we suppose that $N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)$ $\neq \emptyset$.

Let $x$ be a vertex in $N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)$. Let $P^{\prime}=P^{\prime}\left(x, x^{\prime}\right)$ be an $(x, P-\{u, v\})$-path with all internal vertices in $H-P$. Then $P_{1}=P\left[u, x^{\prime}\right] x^{\prime} P^{\prime}$ and $P_{2}=P^{\prime} x^{\prime} P\left[x^{\prime}, v\right]$ are two $C$-paths with end-vertices $u, x$ and $x, v$, respectively, and with all internal vertices in $H$. Clearly, the length of $P_{1}$ and $P_{2}$ are at least 2. By induction hypothesis,

$$
\begin{aligned}
& l(\vec{C}[u, x]) \geq l\left(P_{1}\right)+2\left|N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, x^{-}\right]\right)\right| \\
& l(\vec{C}[x, v]) \geq l\left(P_{2}\right)+2\left|N_{C}(H) \cap V\left(\vec{C}\left[x^{+}, v^{-}\right]\right)\right|
\end{aligned}
$$

Note that $l\left(P_{1}\right)+l\left(P_{2}\right)=l(P)+2 l\left(P^{\prime}\right) \geq l(P)+2$, and

$$
\begin{aligned}
\left|N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, x^{-}\right]\right)\right| & +\left|N_{C}(H) \cap V\left(\vec{C}\left[x^{+}, v^{-}\right]\right)\right| \\
& =\left|N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)\right|-1
\end{aligned}
$$

We have

$$
l(\vec{C}[u, v])=l(\vec{C}[u, x])+l(\vec{C}[x, v]) \geq l(P)+2\left|N_{C}(H) \cap V\left(\vec{C}\left[u^{+}, v^{-}\right]\right)\right|
$$

The assertion is proved.
Lemma 12. Let $G$ be a graph, $C$ be a longest cycle of $G$ and $H$ be a component of $G-C$.
(1) If $u \in N_{C}(H)$, then $u^{+}, u^{-} \notin N_{C}(H)$.
(2) If $u, v \in N_{C}(H)$, then $u^{+} v^{+}, u^{-} v^{-} \notin E(G)$.

Proof. The assertion (1) can be deduced from Lemma 10. Now we prove the assertion (2).

Suppose that $u, v \in N_{C}(H)$. Then let $P$ be a $(u, v)$-path of length at least 2 with all internal vertices in $H$. If $u^{+} v^{+} \in E(G)$, then

$$
C^{\prime}=\vec{C}\left[u^{+}, v\right] v P u \overleftarrow{C}\left[u, v^{+}\right] v^{+} u^{+}
$$

is a cycle longer than $C$, a contradiction. Thus we conclude that $u^{+} v^{+} \notin E(G)$, and similarly, $u^{-} v^{-} \notin E(G)$.

Let $G$ be a graph and $y z \in E(G)$, we define the contraction of $G$ at $y z$, denoted by $G \cdot y z$, as the graph with $V(G \cdot y z)=V(G) \backslash\{y\}$, and $E(G \cdot y z)=$ $E(G-y) \cup\{x z: x y \in E(G)$ and $x \neq z\}$.

Lemma 13. Let $G$ be a graph and $y z \in E(G)$. If there is a cycle $C$ in $G \cdot y z$, then there is a cycle $C^{\prime}$ in $G$ with length at least $l(C)$ such that $V\left(C^{\prime}\right) \subseteq V(C) \cup\{y\}$.

Proof. If $C$ does not contain $z$, then $C$ is also a cycle of $G$ and we are done. So we assume that $z \in V(C)$. By the definition of contraction, $z z^{+} \in E(G)$ or $y z^{+} \in E(G)$, and $z z^{-} \in E(G)$ or $y z^{-} \in E(G)$. Let

$$
C^{\prime}= \begin{cases}C, & \text { if } z z^{+} \in E(G) \text { and } z z^{-} \in E(G), \\ \vec{C}\left[z, z^{-}\right] z^{-} y z, & \text { if } z z^{+} \in E(G) \text { and } z z^{-} \notin E(G), \\ z y z^{+} \vec{C}\left[z^{+}, z\right], & \text { if } z z^{+} \notin E(G) \text { and } z z^{-} \in E(G), \\ y z^{+} \vec{C}\left[z^{+}, z^{-}\right] z^{-} y, & \text { if } z z^{+} \notin E(G) \text { and } z z^{-} \notin E(G) .\end{cases}
$$

Then $C^{\prime}$ is a required cycle.
We will use the following theorems from [3, 10].
Theorem 14 (Chvátal and Erdös [3]). If $G$ is a graph of order $n \geq 3$ with $\alpha(G) \leq \kappa(G)$, then $G$ is Hamiltonian.

Theorem 15 (O, West and Wu [10]). If $G$ is a graph of order n with $\alpha(G) \geq$ $\kappa(G)$, then $G$ has a cycle of length at least

$$
\frac{\kappa(G)(n+\alpha(G)-\kappa(G))}{\alpha(G)}
$$

Theorem 16 ( O , West and $\mathrm{Wu}[10])$. If $G$ is separable, then $V(G)$ admits a partition $\left(V_{1}, V_{2}\right)$ such that $\alpha(G)=\alpha\left(G\left[V_{1}\right]\right)+\alpha\left(G\left[V_{2}\right]\right)$.

Now we prove some more lemmas.
Lemma 17. Let $G$ be a nonseparable graph. Then for any two distinct vertices $u, v$ of $G, G$ contains $a(u, v)$-path of order at least $\lceil n(G) / \alpha(G)\rceil$.

Proof. If $G$ is complete, then the result is trivially true. Now we assume that $G$ is not complete, i.e., $\alpha(G) \geq 2$. So $G$ is 2-connected. If $\alpha(G) \leq \kappa(G)$, then by Theorem 14, $G$ has a Hamilton cycle $C$, and either $\vec{C}[u, v]$ or $\overleftarrow{C}[u, v]$ is a required path. Now we assume that $\alpha(G)>\kappa(G)$.

Let $C$ be a longest cycle of $G$. By Theorem $15, l(C) \geq 2 n(G) / \alpha(G)$. Since $G$ is 2-connected, we may choose a $(u, C)$-path $P_{1}$ and a $(v, C)$-path $P_{2}$ such that they are vertex-disjoint. Let $u^{\prime}$ and $v^{\prime}$ be the end-vertices of $P_{1}$ and $P_{2}$, respectively, on $C$ (possibly $u=u^{\prime}$ or $v=v^{\prime}$, or both). Then $P_{1} u^{\prime} \vec{C}\left[u^{\prime}, v^{\prime}\right] v^{\prime} P_{2}$ or $P_{1} u^{\prime} \overleftarrow{C}\left[u^{\prime}, v^{\prime}\right] v^{\prime} P_{2}$ is a required path.

Lemma 18. Let $G$ be a 2-connected graph. Let $C$ be a subgraph of $G$ with at least two vertices, and $H$ be an induced subgraph of $G-C$. Then $G$ contains a $C$-path $P$ such that

$$
|V(P) \cap V(H)| \geq\left\lceil\frac{n(H)}{\alpha(H)}\right\rceil
$$

Proof. We use induction on $n(H)$. If $H$ has only one vertex, say $x$, then $n(H)=$ $\alpha(H)=1$. Since $G$ is 2 -connected, there is a $C$-path passing through $x$, which is a required path. Now we assume that $H$ has at least two vertices.

Suppose first that $H$ is nonseparable. Let $P_{1}\left(u, u^{\prime}\right)$ and $P_{2}\left(v, v^{\prime}\right)$ be two vertex-disjoint paths between $H$ and $C$ with all internal vertices in $G-(H \cup C)$, where $u, v \in V(H)$ and $u^{\prime}, v^{\prime} \in V(C)$. By Lemma $17, H$ contains a $(u, v)$-path $P^{\prime}$ of order at least $\lceil n(H) / \alpha(H)\rceil$. Thus $P=P_{1} u P^{\prime} v P_{2}$ is a required path.

Now we suppose that $H$ is separable. By Theorem 16, there is a partition $\left(V_{1}, V_{2}\right)$ of $V(H)$ such that $\alpha(H)=\alpha\left(G\left[V_{1}\right]\right)+\alpha\left(G\left[V_{2}\right]\right)$. Let $H_{1}=G\left[V_{1}\right]$ and $H_{2}=G\left[V_{2}\right]$. Note that $n(H)=n\left(H_{1}\right)+n\left(H_{2}\right)$. It is not hard to see that

$$
\frac{n(H)}{\alpha(H)} \leq \max \left\{\frac{n\left(H_{1}\right)}{\alpha\left(H_{1}\right)}, \frac{n\left(H_{2}\right)}{\alpha\left(H_{2}\right)}\right\} \xlongequal{\text { say }} \frac{n\left(H_{1}\right)}{\alpha\left(H_{1}\right)}
$$

By induction hypothesis, there is a $C$-path $P$ such that

$$
|V(P) \cap V(H)| \geq\left|V(P) \cap V\left(H_{1}\right)\right| \geq\left\lceil\frac{n\left(H_{1}\right)}{\alpha\left(H_{1}\right)}\right\rceil \geq\left\lceil\frac{n(H)}{\alpha(H)}\right\rceil
$$

and $P$ is a required path.
Let $L_{1}$ be the graph obtained from $C_{6}$ by adding a new vertex $x$, and by adding three edges from $x$ to three pairwise nonadjacent vertices of the $C_{6}$, and let $L_{2}=K_{3} \vee 4 K_{1}$. Set

$$
\mathcal{L}=\left\{G: L_{1} \subseteq G \subseteq L_{2}\right\} .
$$

Figure 3. Graphs $L_{1}$ and $L_{2}$.
We prove the following lemma to complete this section.
Lemma 19. Let $G$ be a 2-connected graph with $n(G) \leq 7$ and $x$ be a vertex of $G$ with $d(x) \geq 3$. If there is a longest cycle of $G$ excluding $x$, then $G \in \mathcal{L}$.

Proof. Let $C$ be a longest cycle of $G$ excluding $x$ and let $H$ be the component of $G-C$ containing $x$.

We first suppose that $H$ has at least two vertices. By the 2-connectedness of $G$, there are two independent edges from $H$ to $C$. Let $y y^{\prime}$ and $z z^{\prime}$ be such two edges, where $y, z \in V(H)$ and $y^{\prime}, z^{\prime} \in V(C)$. Let $P$ be a $(y, z)$-path of $H$. Then $P^{\prime}=y^{\prime} y P z z^{\prime}$ is a path with length at least 3. By Lemma $10, l\left(\vec{C}\left[y^{\prime}, z^{\prime}\right]\right) \geq 3$ and $l\left(\overleftarrow{C}\left[y^{\prime}, z^{\prime}\right]\right) \geq 3$. Thus $l(C) \geq 6$. Note that $n(H) \geq 2$, we have $n(G) \geq 8$, a contradiction.

Thus we conclude that $H$ has the only one vertex $x$. By Lemma 12, $x$ cannot be adjacent to two successive vertices on $C$. Since $d(x) \geq 3$, there will be at least three vertices on $C$ adjacent to $x$, and at least three vertices on $C$ nonadjacent to $x$. Thus $l(C) \geq 6$. Since $n(G) \leq 7$ and $x \notin V(C)$, we have $l(C) \leq 6$. Thus $C$
has exactly 6 vertices and $x$ is adjacent to three pairwise nonadjacent vertices of $C$. This implies that $L_{1} \subseteq G$.

Let $C=y_{1} z_{1} y_{2} z_{2} y_{3} z_{3} y_{1}$ such that $N(x)=\left\{y_{1}, y_{2}, y_{3}\right\} . \quad$ By Lemma 12, $\left\{x, z_{1}, z_{2}, z_{3}\right\}$ is an independent set. This implies that $G \subseteq L_{2}$.

## 3. Proofs of main results

In this section, we shall present the proof of main results.
Proof of Theorem 4. Let $C$, with an orientation $\vec{C}$, be a longest cycle of $G$. We assume on the contrary that there is a vertex $x$ in $V(G-C)$ with $d(x) \geq d=$ $\max \{\lceil n / 2\rceil, n-3 k+2\}$.

An $(x, C)$-fan is a collection of $(x, C)$-paths such that they have the only vertex $x$ in common. Since $G$ is $k$-connected, there is an $(x, C)$-fan with $s \geq k$ paths $P_{i}=P_{i}\left(x, z_{i}\right), 1 \leq i \leq s$, where $z_{i} \in V(C)$. We choose the $(x, C)$-fan such that $s$ is as large as possible. We suppose that $z_{1}, z_{2}, \ldots, z_{s}$ appear in this order along $\vec{C}$. Thus

$$
\begin{equation*}
l(C)=\sum_{i=1}^{s} l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right) \tag{1}
\end{equation*}
$$

where the subscripts are taken modulo $s$.
By Menger's theorem, there is a vertex $y_{i} \in V\left(P_{i}-x\right)$ such that $S=\left\{y_{i}\right.$ : $1 \leq i \leq s\}$ is a vertex-cut of $G$ separating $x$ and $C-S$. We choose $y_{i}$ in such a way that $d_{P_{i}}\left(x, y_{i}\right)$ is as small as possible (note that $y_{i}$ is possibly equal to $z_{i}$ ). Clearly

$$
\begin{equation*}
N_{C}(x) \subseteq S \tag{2}
\end{equation*}
$$

Let $H$ be the component of $G-S$ containing $x$. Then
Claim 20. For every vertex $y_{i} \in S$, either $N_{H}\left(y_{i}\right)=\{x\}$ or $\left|N_{H}\left(y_{i}\right)\right| \geq 2$.
Proof. Suppose on the contrary that $\left|N_{H}\left(y_{i}\right)\right|=1$ and $y_{i}^{\prime} \neq x$ is the vertex in $N_{H}\left(y_{i}\right)$. Then $y_{i}^{\prime}$ is the neighbor of $y_{i}$ on $P_{i}\left[x, y_{i}\right]$. Let $S^{\prime}=\left(S \backslash\left\{y_{i}\right\}\right) \cup\left\{y_{i}^{\prime}\right\}$. Then $S^{\prime}$ is a vertex-cut of $G$ separating $x$ and $C-S^{\prime}$ such that $d_{P_{i}}\left(x, y_{i}^{\prime}\right)<d_{P_{i}}\left(x, y_{i}\right)$, contradicting the choice of $S$.

If $H$ has only one vertex $x$, then $d(x)=|S|=s$. By Lemma $12, l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right)$ $\geq 2$ for all $i \in\{1,2, \ldots, s\}$. By $(1), l(C) \geq 2 s=2 d(x)$ and

$$
n \geq l(C)+1 \geq 2 d(x)+1 \geq n+1
$$

a contradiction.

If $H$ has exactly two vertices, then let $x^{\prime}$ be the vertex in $V(H) \backslash\{x\}$. By Claim 20, every vertex $y_{i}$ in $S$ is adjacent to $x$. Hence $N(x)=S \cup\left\{x^{\prime}\right\}$ and $s=$ $d(x)-1$. Note that $d\left(x^{\prime}\right)=d_{S}\left(x^{\prime}\right)+1$ and $d\left(x^{\prime}\right) \geq k$, since $G$ is $k$-connected. We have $d_{S}\left(x^{\prime}\right) \geq k-1$. By Lemma $12, l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right) \geq 2$ for all $i$. Moreover, if $x^{\prime} y_{i} \in$ $E(G)$, then $P=P_{i}\left[z_{i}, y_{i}\right] y_{i} x^{\prime} x y_{i+1} P_{i+1}\left[y_{i+1}, z_{i+1}\right]$ is a $C$-path of length at least 3, by Lemma $10, l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right) \geq 3$. This implies that $l(C)=\sum_{i=1}^{s} l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right) \geq$ $3 d_{S}\left(x^{\prime}\right)+2\left(s-d_{S}\left(x^{\prime}\right)\right) \geq 2 s+d_{S}\left(x^{\prime}\right) \geq 2 d(x)+k-3 \geq n+k-3$, and $n \geq$ $l(C)+2 \geq n+k-1 \geq n+1$, a contradiction.

Now it remains to consider the case when $H$ has at least three vertices.
By $b(x)$ we denote the number of vertices in $V(G) \backslash N[x]$. Then $b(x)=n-$ $1-d(x) \leq 3 k-3$. Hence, by (2),

$$
\begin{equation*}
l(C) \leq s+b(x) \leq s+3 k-3 \tag{3}
\end{equation*}
$$

Claim 21. Every vertex in $V(H) \backslash\{x\}$ is not a cut-vertex of $H$.
Proof. Suppose, otherwise, that $x^{\prime} \neq x$ is a cut-vertex of $H$. Let $H_{1}$ and $H_{2}$ be two components of $H-x^{\prime}$ such that $x \in V\left(H_{1}\right)$.

We claim that for every vertex $y_{i} \in S, N_{H_{1}}\left(y_{i}\right) \neq \emptyset$. Otherwise, every $\left(x, y_{i}\right)-$ path with all internal vertices in $H$ will pass through $x^{\prime}$, so is $P_{i}\left[x, y_{i}\right]$. Let $S^{\prime}=\left(S \backslash\left\{y_{i}\right\}\right) \cup\left\{x^{\prime}\right\}$. Then $S^{\prime}$ is a vertex-cut of $G$ separating $x$ and $C-S^{\prime}$ such that $d_{P_{i}}\left(x, x^{\prime}\right)<d_{P_{i}}\left(x, y_{i}\right)$, a contradiction. Thus as we claimed, $N_{H_{1}}\left(y_{i}\right) \neq \emptyset$.

For every $y_{i} \in S$, let $w_{i}$ be a vertex in $N_{H_{1}}\left(y_{i}\right)$. Now we claim that $l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right) \geq 4$ for those $i$ such that $N_{H_{2}}\left(y_{i}\right) \neq \emptyset$. Suppose $N_{H_{2}}\left(y_{i}\right) \neq \emptyset$. Let $w_{i}^{\prime}$ be a neighbor of $y_{i}$ in $H_{2}$. Then $H$ has a ( $w_{i}^{\prime}, w_{i+1}$ )-path $P$ of length at least 2. Thus $P^{\prime}=P_{i}\left[z_{i}, y_{i}\right] y_{i} w_{i}^{\prime} P w_{i+1} y_{i+1} P_{i+1}\left[y_{i+1}, z_{i+1}\right]$ is a path of length at least 4 with all internal vertices in $G-C$. By Lemma $10, l\left(\vec{C}\left[z_{i}, z_{i+1}\right]\right) \geq 4$.

Note that $\left|N_{S}\left(H_{2}\right)\right| \geq k-1$, since $G$ is $k$-connected and $N_{S}\left(H_{2}\right) \cup\left\{x^{\prime}\right\}$ is a vertex-cut. Therefore,

$$
l(C) \geq 4(k-1)+2(s-k+1)=2 s+2 k-2 \geq s+3 k-2
$$

contradicting (3).
Claim 22. $H$ is a star with center $x$.
Proof. Suppose, otherwise, $H$ has an $x$-path $x x^{\prime} x^{\prime \prime}$ (say) of length 2. Then there is an $\left(x^{\prime \prime}, S\right)$-fan with $k$ internally disjoint paths $Q_{i}=Q_{i}\left(x^{\prime \prime}, y_{j_{i}}\right), 1 \leq j_{1}<$ $j_{2}<\cdots<j_{k} \leq s$, such that they have the only vertex $x^{\prime \prime}$ in common. We set $S^{\prime}=\left\{y_{j_{i}}: 1 \leq i \leq k\right\}$.

Note that at most one path of $Q_{i}$ passes through $x$. We will prove that $l\left(\vec{C}\left[z_{j_{i}}, z_{j_{i}+1}\right]\right) \geq 4$ for those $j_{i}$ such that $y_{j_{i}} \in S^{\prime}$ and $Q_{i}$ does not pass through $x$.

Suppose that $y_{j_{i}} \in S^{\prime}$ and $Q_{i}$ does not pass through $x$. Let $w_{j_{i}}$ be the neighbor of $y_{j_{i}}$ on $Q_{i}$. Then $w_{j_{i}} \neq x$. If $l\left(Q_{i}\right) \geq 2$, then let $v_{j_{i}}$ be a neighbor of $w_{j_{i}}$ on the path $Q_{i}\left[x^{\prime \prime}, w_{j_{i}}\right]$; if $l\left(Q_{i}\right)=1$, then $\left(w_{j_{i}}=x^{\prime \prime}\right.$ and) we let $v_{j_{i}}=x^{\prime}$. Then $v_{j_{i}} \neq x$. By Claim 20, $y_{j_{i}+1}$ has a neighbor $w_{j_{i}+1}^{\prime}$ in $H$ other that $w_{j_{i}}$. We claim that $H$ has a $\left(w_{j_{i}}, w_{j_{i}+1}^{\prime}\right)$-path of length at least 2. Otherwise $w_{j_{i}} w_{j_{i}+1}^{\prime} \in$ $E(G)$ and $w_{j_{i}} w_{j_{i}+1}^{\prime}$ is a cut-edge of $H$. By Claim 21, every vertex of $V(H) \backslash\{x\}$ is not a cut-vertex of $H$. This implies that $w_{j_{i}+1}^{\prime}=x$ and $w_{j_{i}}$ has only one neighbor $x$ in $H$, contradicting the fact that $v_{j_{i}} \in N_{H}\left(w_{j_{i}}\right)$ and $v_{j_{i}} \neq x$. Thus as we claimed, $H$ has a $\left(w_{j_{i}}, w_{j_{i}+1}^{\prime}\right)$-path $P$ of length at least 2 . Thus $P^{\prime}=$ $P_{j_{i}}\left[z_{j_{i}}, y_{j_{i}}\right] y_{j_{i}} w_{j_{i}} P w_{j_{i}+1}^{\prime} y_{j_{i}+1} P_{j_{i}+1}\left[y_{j_{i}+1}, z_{j_{i}+1}\right]$ is a path of length at least 4 with all internal vertices in $G-C$. By Lemma $10, l\left(\vec{C}\left[z_{j_{i}}, z_{j_{i}+1}\right]\right) \geq 4$.

Thus we conclude that there are at least $k-1$ segments $\vec{C}\left[z_{i}, z_{i+1}\right]$ of length at least 4. Hence

$$
l(C) \geq 4(k-1)+2(s-k+1)=2 s+2 k-2 \geq s+3 k-2,
$$

a contradiction.
By Claim 22, $H=K_{1, n(H)-1}$. Let

$$
\begin{array}{ll}
S_{0}=\left\{y_{i} \in S: N_{H}\left(y_{i}\right)=\{x\}\right\}, & S_{2}=S \backslash\left(S_{0} \cup S_{1}\right), \\
S_{1}=\left\{y_{i} \in S:\left|N_{H}\left(y_{i}\right) \backslash\{x\}\right|=1\right\}, & s_{i}=\left|S_{i}\right|, \quad i \in\{0,1,2\} .
\end{array}
$$

Thus $s=s_{0}+s_{1}+s_{2}$.
Let $y_{j_{i}}, 1 \leq j_{1}<j_{2}<\cdots<j_{s_{1}+s_{2}} \leq s$, be the vertices in $S_{1} \cup S_{2}$. Since $G$ is $k$-connected,

$$
\begin{equation*}
s_{1}+s_{2} \geq\left|N_{S}\left(x^{\prime}\right)\right| \geq k-1 \tag{4}
\end{equation*}
$$

for any $x^{\prime} \in V(H) \backslash\{x\}$, and

$$
\begin{equation*}
s_{1}+(n(H)-1) s_{2} \geq|E(H-x, S)| \geq(k-1)(n(H)-1) . \tag{5}
\end{equation*}
$$

If $s_{1}+s_{2}=1$, then without loss of generality we assume that $x^{\prime} y_{1} \in E(G)$, where $x^{\prime} \in V(H) \backslash\{x\}$ and $y_{1} \in S_{1} \cup S_{2}$. Note that $\left\{x, y_{1}\right\}$ is a vertex-cut of $G$, implying that $k=2$. Since $z_{1} P_{1}\left[z_{1}, y_{1}\right] y_{1} x^{\prime} x y_{2} P_{2}\left[y_{2}, z_{2}\right]$ is a path of length at least 3 , by Lemma $10, l\left(\vec{C}\left[z_{1}, z_{2}\right]\right) \geq 3$ and by symmetry, $l\left(\vec{C}\left[z_{1}, z_{s}\right]\right) \geq 3$. Thus

$$
l(C) \geq 3+3+2(s-2)=2 s+2>s+3 k-3,
$$

a contradiction. Now we conclude that $s_{1}+s_{2} \geq 2$.

Claim 23. For every vertex $y_{j_{i}} \in S_{1} \cup S_{2}$,

$$
l\left(\vec{C}\left[z_{j_{i}}, z_{j_{i+1}}\right]\right) \geq \begin{cases}3+2 \mid N_{C}(x) \cap V\left(\vec{C}\left[z_{j_{i}}^{+}, z_{j_{i+1}}^{-}\right)\right) ; & y_{j_{i}} \in S_{1}, \\ 4+2\left|N_{C}(x) \cap V\left(\vec{C}\left[z_{j_{i}}^{+}, z_{j_{i+1}}^{-}\right]\right)\right| ; & y_{j_{i}} \in S_{2},\end{cases}
$$

where the subsubscripts are taken modulo $s_{1}+s_{2}$.
Proof. For any $y_{j_{i}} \in S_{1} \cup S_{2}$, we let $w_{j_{i}}$ be a vertex in $N_{H}\left(y_{j_{i}}\right) \backslash\{x\}$. If $y_{j_{i}} \in S_{1}$, then by Claim 20, $y_{j_{i}} x \in E(G)$. Thus

$$
P=P_{j_{i}}\left[z_{j_{i}}, y_{j_{i}}\right] y_{j_{i}} x w_{j_{i+1}} y_{j_{i+1}} P_{j_{i+1}}\left[y_{j_{i+1}}, z_{j_{i+1}}\right]
$$

is a $C$-path of length at least 3. If $y_{j_{i}} \in S_{2}$, then let $w_{j_{i}}^{\prime}$ be a vertex in $N_{H}\left(y_{j_{i}}\right) \backslash$ $\left\{x, w_{j_{i+1}}\right\}$. Thus $P=P_{j_{i}}\left[z_{j_{i}}, y_{j_{i}}\right] y_{j_{i}} w_{j_{i}}^{\prime} x w_{j_{i+1}} y_{j_{i+1}} P_{j_{i+1}}\left[y_{j_{i+1}}, z_{j_{i+1}}\right]$ is a $C$-path of length at least 4. Note that $N_{C}(H) \cap V\left(\vec{C}\left[z_{j_{i}}^{+}, z_{j_{i+1}}^{-}\right]\right)=N_{C}(x) \cap V\left(\vec{C}\left[z_{j_{i}}^{+}, z_{j_{i+1}}^{-}\right]\right)$. By Lemma 11, we have the assertion.

Note that $\sum_{i=1}^{s_{1}+s_{2}}\left|N_{C}(x) \cap V\left(\vec{C}\left[z_{j_{i}}^{+}, z_{j_{i+1}}^{-}\right]\right)\right|=s_{0}$. By Claim 23,

$$
l(C)=\sum_{i=1}^{s_{1}+s_{2}} l\left(\vec{C}\left[z_{j_{i}}, z_{j_{i+1}}\right]\right) \geq 2 s_{0}+3 s_{1}+4 s_{2}=2 s+s_{1}+2 s_{2}
$$

By (4) and (5), we have

$$
\begin{aligned}
l(C) & \geq 2 s+s_{1}+2 s_{2}=2 s+\frac{n(H)-3}{n(H)-2}\left(s_{1}+s_{2}\right)+\frac{1}{n(H)-2}\left(s_{1}+(n(H)-1) s_{2}\right) \\
& \geq 2 s+\frac{n(H)-3}{n(H)-2}(k-1)+\frac{n(H)-1}{n(H)-2}(k-1)=2 s+2 k-2 \geq s+3 k-2
\end{aligned}
$$

a contradiction.
The proof is complete.
Proof of Theorem 5. If $\alpha \leq \kappa(G)$, then $G$ is Hamiltonian by Theorem 14 and we are done. Now suppose that $\alpha>\kappa(G)$. Let $C$ be a longest cycle of $G$ with an orientation, $\vec{C}$. Assume for contradiction that there exists a vertex $x$ of degree more than $d_{0}$ such that $x \notin V(C)$. Let $H$ be the component of $G-C$ containing $x$. Then $\left|N_{C}(H)\right| \geq k$, since $G$ is $k$-connected. Let $N_{C}(H)=\left\{z_{1}, z_{2}, \ldots, z_{s}\right\}$, where $s=\left|N_{C}(H)\right|$. Hence

$$
\begin{equation*}
d(x) \leq|V(H-x)|+\left|N_{C}(H)\right| \leq n+s-l(C)-1 . \tag{6}
\end{equation*}
$$

By Lemma $12,\left\{x, z_{1}^{+}, z_{2}^{+}, \ldots, z_{s}^{+}\right\}$is an independent set of $G$. Thus, we obtain that $s+1 \leq \alpha$. Therefore, by (6) and by the hypothesis of $d(x)>d_{0}$ and by Theorem 15 ,

$$
\begin{aligned}
d_{0}<d(x) \leq n+s-l(C)-1 & \leq n+\alpha-1-\frac{\kappa(G)(n+\alpha-\kappa(G))}{\alpha}-1 \\
& =n+\alpha-2-\frac{\kappa(G)(n+\alpha-\kappa(G))}{\alpha}=d_{0}
\end{aligned}
$$

a contradiction. This completes the proof of Theorem 5 .
In order to use the induction method, we prove the following stronger theorem instead of Theorem 7.
Theorem 24. Suppose $\alpha \geq 4$ and $n \geq 3$ are two integers and $d$ is defined as in Theorem 7. Let $G$ be a 2-connected graph with $n(G) \leq n$ and $\alpha(G) \leq \alpha$. Then every longest cycle of $G$ contains all the vertices of degree at least $d$, unless $G \in \mathcal{L}$.

Proof. We use induction on $n(G)$. If $G$ has only three or four vertices, then $G$ is Hamiltonian and the result is trivially true. Now we assume that $G$ has at least five vertices and assume that the assertion holds for all graphs with order less than $n(G)$. This implies that $n \geq 5$ and $q \geq 0$.

Suppose that $q=0$. Then $r=n-5$. If $n \leq 7$, then $r \leq 2$ and $d=3$. By Lemma $19, G \in \mathcal{L}$ or every longest cycle contains all vertices of degree at least $d$. If $n \geq 8$, then $r \geq 3$ and $d=r+1=n-4$. By Theorem 1 , every longest cycle contains all vertices of degree at least $d$. Thus we are done. So in the following, we assume that $q \geq 1$ (i.e., $n \geq \alpha+5$ ).

Let $C$ be a longest cycle of $G$. We suppose on the contrary that there is a vertex $x$ in $V(G-C)$ with $d(x) \geq d$. Let $H$ be the component of $G-C$ containing $x$.

Let $b=n-1-d$. Then

$$
b= \begin{cases}2 q+r+1, & 0 \leq r \leq 2 \\ 2 q+3, & 3 \leq r<\alpha\end{cases}
$$

By $b(x)$ we denote the number of vertices in $V(G) \backslash N[x]$. Then

$$
\begin{equation*}
b(x) \leq b \leq 2 q+3 . \tag{7}
\end{equation*}
$$

Suppose first that $H$ has only one vertex $x$. By Lemma 12, $x$ is nonadjacent to every vertex of $N_{C}^{+}(x)$. Thus $b \geq b(x) \geq d(x) \geq d$. By comparing the formulas of $b$ and $d$, we can see that $r=2$ and $\alpha=4$. Since $q \geq 1$, we have $d \geq \alpha+1 \geq 5$. But in this case $N_{C}^{+}(x)$ is an independent set with $d(x) \geq 5$ vertices, a contradiction. This implies that $H$ has at least two vertices.

Note that

$$
d-\alpha= \begin{cases}(q-1)(\alpha-2)+1, & 0 \leq r \leq 2 \\ (q-1)(\alpha-2)+r-1, & 3 \leq r<\alpha\end{cases}
$$

We have $d-\alpha \geq(q-1)(\alpha-2)+1$, and

$$
\begin{equation*}
\left\lceil\frac{d-\alpha}{\alpha-2}\right\rceil \geq\left\lceil\frac{(q-1)(\alpha-2)+1}{\alpha-2}\right\rceil=q . \tag{8}
\end{equation*}
$$

Suppose that there is some component of $G-C$ other than $H$. Let $G^{\prime}$ be the graph obtained from $G$ by removing all other components of $G$, i.e., $G^{\prime}=$ $G[V(C) \cup V(H)]$. Then $G^{\prime}$ is 2-connected, $n\left(G^{\prime}\right)<n(G), \alpha\left(G^{\prime}\right) \leq \alpha(G)$, and $d_{G^{\prime}}(x)=d(x)$. By induction hypothesis, every longest cycle of $G^{\prime}$ contains $x$. This implies that there is a cycle in $G^{\prime}$, and then in $G$, longer than $C$, a contradiction. Hence we conclude that there is only one component $H$ of $G-C$, i.e., $G-C=H$.

Claim 25. $N(x)=\left(V(H) \cup N_{C}(H)\right) \backslash\{x\}$.
Proof. Suppose that there is a vertex $y$ in $H$ such that $x y \notin E(G)$. We choose a vertex $z \in N(y)$ in such a way that if $G-y$ is 2 -connected, then let $z$ be an arbitrary neighbor of $y$; if $G-y$ is separable, then let $z$ be a neighbor of $y$ which is an inner-vertex of some end-block of $G-y$. In any case, $\{y, z\}$ is not a vertex-cut and thus $G^{\prime}=G \cdot y z$ is 2 -connected. Note that $n\left(G^{\prime}\right)<n(G), \alpha\left(G^{\prime}\right) \leq \alpha(G)$, and $d_{G^{\prime}}(x)=d(x)$. By induction hypothesis, every longest cycle of $G^{\prime}$ contains $x$. This implies that there is a cycle in $G^{\prime}$ longer than $C$. But if $G^{\prime}$ contains such a cycle, then so is $G$ by Lemma 13, a contradiction. This implies that $x$ is adjacent to all the vertices in $V(H) \backslash\{x\}$.

Note that every vertex in $V(H) \backslash\{x\}$ is not a cut-vertex of $H$. Suppose that there is a vertex $z$ in $N_{C}(H)$ such that $x z \notin E(G)$. It is not difficult to see that there is a neighbor $y$ of $z$ in $H$ such that $\{y, z\}$ is not a vertex-cut of $G$. Thus $G^{\prime}=G \cdot y z$ is 2-connected. Note that $n\left(G^{\prime}\right)<n(G), \alpha\left(G^{\prime}\right) \leq \alpha(G)$, and $d_{G^{\prime}}(x)=d(x)$. By induction hypothesis, every longest cycle of $G^{\prime}$ contains $x$. This implies that there is a cycle in $G^{\prime}$, and then in $G$, longer than $C$, a contradiction. Now we conclude that $x$ is adjacent to all the vertices in $\left(V(H) \cup N_{C}(H)\right) \backslash\{x\}$.

By Claim 25, $\alpha(H)=\alpha(H-x)$ and $d_{H}(x)=n(H-x)$. By Lemma 18, there is a $C$-path $P=P(u, v)$ such that

$$
|V(P) \cap V(H-x)| \geq\left\lceil\frac{n(H-x)}{\alpha(H-x)}\right\rceil=\left\lceil\frac{d_{H}(x)}{\alpha(H)}\right\rceil .
$$

By Claim 25, we can choose $P$ such that it satisfies the above inequality and $x \in V(P)$. Thus

$$
|V(P)| \geq|V(P) \cap V(H-x)|+|\{u, v, x\}| \geq\left\lceil\frac{d_{H}(x)}{\alpha(H)}\right\rceil+3 .
$$

By Claim $25, d_{H}(x)=d(x)-\left|N_{C}(H)\right| \geq d-\left|N_{C}(H)\right|$. Note that the union of $N_{C}^{+}(H)$ and an independent set of $H$ form an independent set of $G$. This implies that $\alpha(H) \leq \alpha(G)-\left|N_{C}(H)\right| \leq \alpha-\left|N_{C}(H)\right|$. Together with the above inequality, we have

$$
|V(P)| \geq\left\lceil\frac{d-\left|N_{C}(H)\right|}{\alpha-\left|N_{C}(H)\right|}\right\rceil+3=\left\lceil\frac{d-\alpha}{\alpha-\left|N_{C}(H)\right|}\right\rceil+4 \geq\left\lceil\frac{d-\alpha}{\alpha-2}\right\rceil+4
$$

By (8), $l(P)=|V(P)|-1 \geq q+3$. By Lemma 11,

$$
l(C)=l(\vec{C}[u, v])+l(\vec{C}[v, u]) \geq 2 l(P)+2\left(\left|N_{C}(H)\right|-2\right) \geq 2 q+2\left|N_{C}(H)\right|+2
$$

Thus

$$
b(x)=\left|V(C) \backslash N_{C}(H)\right| \geq 2 q+2\left|N_{C}(H)\right|+2-\left|N_{C}(H)\right| \geq 2 q+4
$$

contradicting (7).
The proof is complete.
Proof of Theorem 8. The case $n=\alpha+2$ is trivial. The only 2 -connected graphs with independent number $\alpha$ and order $\alpha+2$ are $K_{2, \alpha}$ and $K_{1,1, \alpha}$. Note that every longest cycle of them contains all (the two) vertices with degree at least 3. For the case $n=\alpha+4$, the bound on $d$ in Theorems 7 and 8 are equal. So the result can be deduced by Theorem 7 immediately.

Now we consider the case $n=\alpha+3$. Let $G$ be a 2 -connected graph with independent number $\alpha$ and order $\alpha+3$, let $C$ be an arbitrary longest cycle of $G$, and let $x$ be a vertex of $G$ of degree at least 4 . If $C$ contains $x$, then we have nothing to prove. So we assume that $x \in V(G-C)$. If $x$ is an isolated vertex of $G-C$, then $d_{C}(x)=d(x) \geq 4$. By Lemma $12, l(C) \geq 8$. Thus

$$
\begin{aligned}
\alpha(G) & \leq \alpha(G[V(C)])+\alpha(G-C) \leq \alpha(C)+|V(G-C)|=\left\lfloor\frac{l(C)}{2}\right\rfloor+n-l(C) \\
& =n-\left\lceil\frac{l(C)}{2}\right\rceil \leq n-4
\end{aligned}
$$

a contradiction. Thus we conclude that $x$ has a neighbor $x^{\prime}$ in $G-C$. Since $G$ is 2-connected, $G$ has a $C$-path $P$ passing through the edge $x x^{\prime}$. Note that $l(P) \geq 3$, and by Lemma $10, l(C) \geq 6$. Thus

$$
\begin{aligned}
\alpha(G) & \leq \alpha(G[V(C)])+\alpha(G-C) \leq\left\lfloor\frac{l(C)}{2}\right\rfloor+n-l(C)-1 \\
& =n-\left\lceil\frac{l(C)}{2}\right\rceil-1 \leq n-4
\end{aligned}
$$

a contradiction.
