# REQUIRING THAT MINIMAL SEPARATORS INDUCE COMPLETE MULTIPARTITE SUBGRAPHS 

Terry A. McKee<br>Department of Mathematics and Statistics<br>Wright State University<br>Dayton, Ohio 45435 USA<br>e-mail: terry.mckee@wright.edu

#### Abstract

Complete multipartite graphs range from complete graphs (with every partite set a singleton) to edgeless graphs (with a unique partite set). Requiring minimal separators to all induce one or the other of these extremes characterizes, respectively, the classical chordal graphs and the emergent unichord-free graphs. New theorems characterize several subclasses of the graphs whose minimal separators induce complete multipartite subgraphs, in particular the graphs that are 2 -clique sums of complete, cycle, wheel, and octahedron graphs.

Keywords: minimal separator, complete multipartite graph, chordal graph, unichord-free graph.
2010 Mathematics Subject Classification: 05C62, 05C75, 05C69.

## 1. Introduction and Terminology

Define a complete-multipartite-separator graph to be a graph in which every minimal separator (as defined later in this section) induces a complete multipartite subgraph. As one special case, the graphs in which every minimal separator induces a complete graph are precisely the chordal graphs, a classic graph class with many characterizations, the most common being that every cycle of length 4 or more has at least one chord; see $[1,7]$. At the other extreme, the graphs for which every minimal separator induces an edgeless subgraph are precisely the unichordfree graphs, a recent graph class whose name comes from the characterization that no cycle has exactly one chord; see $[2,3,4,6,8]$.

Section 2 will characterize the complete-multipartite-separator graphs, which include all complete multipartite graphs, all chordal graphs, and all unichord-free
graphs. But this characterization fails to generalize the existing characterizations of chordal graphs and unichord-free graphs. Section 3 will remedy this, along with generalizing these previously studied classes to increasingly larger subclasses of complete-multipartite-separator graphs.

For any set $S$ of vertices of a graph $G$, let $G[S]$ denote the subgraph of $G$ induced by $S$ and let $G-S$ denote $G[V(G)-S]$. Let $\bar{G}$ denote the graph complement of $G$ and, for every graph $H$, define $G$ to be $H$-free if no induced subgraph of $G$ is isomorphic to $H$. A chord of a cycle $C$ is an edge $v w$ with $v, w \in V(C)$ and yet $v w \notin E(C)$. Let $C_{n}$ and $P_{n}$ denote, respectively, the cycle and path of order $n$ (so $P_{n}$ has length $n-1$ ). For any $x$-to- $y$ path $\pi$, let $\pi^{\circ}=$ $V(\pi)-\{x, y\}$ be the set of internal vertices of $\pi$.

For nonadjacent vertices $v$ and $w$ in a connected graph $G$, a $v, w$-separator of $G$ is a set $S \subseteq V(G)-\{v, w\}$ such that $v$ and $w$ are in different components (maximal connected subgraphs) of $G-S$, and a vertex separator of $G$ is a $v, w$-separator for some $v, w \in V(G)$. A minimal $v, w$-separator of $G$ is a $v, w$-separator that is not a proper subset of another $v, w$-separator, and a minimal separator of $G$ is a minimal $v, w$-separator for some $v, w \in V(G)$. This means that one minimal separator can be contained in another one, since a minimal $v, w$-separator might be contained in a minimal $v^{\prime}, w^{\prime}$-separator. See [1] for more about minimal separators, including that a vertex separator $S$ of $G$ is a minimal separator of $G$ if and only if, for some two components $G_{1}$ and $G_{2}$ of $G-S$, each vertex in $S$ has a neighbor in each $G_{i}$.

A complete $k$-partite graph $G$ has $V(G)$ partitioned into $k \geq 1$ nonempty partite sets $V_{1}, \ldots, V_{k}$ where $E(G)=\left\{x y:(x, y) \in V_{i} \times V_{j}\right.$ with $\left.i \neq j\right\}$; denote $G$ by $K\left(n_{1}, \ldots, n_{k}\right)$ where each $n_{i}=\left|V_{i}\right|$ and $1 \leq n_{1} \leq \cdots \leq n_{k}$. A complete multipartite graph is a complete $k$-partite graph for some $k \geq 1$. Therefore-as will be used several times in the following sections - a graph is complete multipartite if and only if it has no induced subgraph $H \cong \overline{P_{3}}=K_{1} \cup K_{2}$ (if, say, $V(H)=\{x, y, z\}$ with $E(H)=\{x y\}$, then $x$ and $y$ would have to be in the same partite set as $z$ in a complete multipartite graph, but then they would not be adjacent to each other.) The two extremes among complete multipartite graphs are the complete graphs $K_{n}=K(1, \ldots, 1)$ ( $n$-partite with each $n_{i}=1$ ) and the edgeless graphs $\overline{K_{n}}=K(n)$ (1-partite with the unique $n_{i}=n_{1}=n$ ).

## 2. When Each $G[S]$ is Complete Multipartite

Lemma 1. Every minimal separator of an induced subgraph of $G$ is contained in a minimal separator of $G$.

Proof. Suppose $S_{0}$ is a minimal $v, w$-separator of an induced subgraph $H_{0}$ of $G$ such that $H_{0}-S_{0}$ has components $H_{0}\left[R_{0}\right]$ and $H_{0}\left[R_{0}^{\prime}\right]$ where $v \in R_{0}, w \in R_{0}^{\prime}$, and each vertex in $S_{0}$ has neighbors in both $R_{0}$ and $R_{0}^{\prime}$.

Suppose $S_{0}$ is not a $v, w$-separator of $G$, which means that $G-S_{0}$ is connected by a $v$-to- $w$ path $\pi_{1}$ containing some $x_{1} \in V\left(\pi_{1}^{\circ}\right)-V\left(H_{0}\right)$. Thus, $S_{0} \cup\left\{x_{1}\right\}$ is contained in a $v, w$-separator $S_{1}$ of an induced subgraph $H_{1}$ of $G$ such that $H_{1}-S_{1}$ has components $H_{1}\left[R_{1}\right]$ and $H_{1}\left[R_{1}^{\prime}\right]$ with $R_{1}=R_{0} \cup \tau^{\circ}$ where $\tau$ is the $v$-to- $x_{1}$ subpath of $\pi_{1}$, and $R_{1}^{\prime}=R_{0}^{\prime} \cup\left(\tau^{\prime}\right)^{\circ}$ where $\tau^{\prime}$ is the $x_{1}$-to- $w$ subpath of $\pi_{1}$. As in [1], $S_{1}$ is a minimal $v, w$-separator since each vertex of $S_{0}$ has neighbors in both $R_{0}$ and $R_{0}^{\prime}$ (and so in both $R_{1}$ and $R_{1}^{\prime}$ ), and each vertex of $S_{1}-S_{0}$ has neighbors in both $\tau$ and $\tau^{\prime}$ (and so in both $R_{1}$ and $R_{1}^{\prime}$ ).

Repeat this, sequentially forming larger sets $S_{i}$ by choosing $x_{i} \in V\left(\pi_{i}^{\circ}\right)$ in connected graphs $G-S_{i-1}$. As soon as $G-S_{i}$ stops being connected, $S_{i}$ will be a minimal separator of $G$ that contains $S_{0}$.

If $v w$ is a chord of $C$ and $x, y \in V(C)-\{v, w\}$, say that $v w$ crosses $\{x, y\}$ if the four vertices $v, x, w, y$ come in that order around $C$. For disjoint subsets $S_{1}, S_{2} \subset V(C)$, define an $S_{1}$-to- $S_{2}$ chord of $C$ to be a chord $x y$ where $x \in S_{1}$ and $y \in S_{2}$. A theta graph $\Theta=\Theta\left(u, w ; \pi_{1}, \pi_{2}, \pi_{3}\right)$ of a graph $G$ consists of nonadjacent vertices $u$ and $w$ along with three internally-disjoint chordless $u$-to- $w$ paths $\pi_{1}$, $\pi_{2}$, and $\pi_{3}$. Define a chord of $\Theta$ to be a chord of a cycle $\pi_{i} \cup \pi_{j}$ with $i \neq j$, and define a transversal of $\Theta$ to be any $\left\{z_{1}, z_{2}, z_{3}\right\}$ where each $z_{i} \in \pi_{i}^{\circ}$. Thus a transversal of $\Theta$ is a minimal $u, v$-separator of $\Theta$ (but not necessarily of $G[V(\Theta)]$, because chords of $\Theta$ will be edges of $G[V(\Theta)])$. Say that a transversal $\left\{z_{1}, z_{2}, z_{3}\right\}$ of $\Theta$ is crossed by a chord of $\Theta$ if some $x y \in E(G)$ has $x$ an internal vertex of some $u$-to- $z_{i}$ subpath of $\pi_{i}$ and $y$ an internal vertex of some $z_{j}$-to- $w$ subpath of $\pi_{j} \neq \pi_{i}$.

Recall that complete-multipartite-separator graphs are those in which every minimal separator induces a complete multipartite subgraph. Theorem 2 is equivalent to a result in [5] (which contains a more general discussion of restrictions on minimal separators).

Theorem 2. A graph $G$ is a complete-multipartite-separator graph if and only if, for every theta subgraph $\Theta$ of $G$ with transversal $S$, if $G[S] \cong \overline{P_{3}}$, then $S$ is crossed by a chord of $\Theta$.
Proof. First, suppose $G$ is a complete-multipartite-separator graph containing a theta subgraph $\Theta=\Theta\left(u, w ; \pi_{1}, \pi_{2}, \pi_{3}\right)$ with transversal $S$ where $G[S] \cong \overline{P_{3}}$. Since complete multipartite graphs are $\overline{P_{3}}$-free, $S$ cannot be contained in a minimal separator of $G[V(\Theta)]$ by Lemma 1. Therefore, since each $\pi_{i}$ is chordless, $S$ is crossed by a chord of $\Theta$.

Conversely, suppose $G$ has a minimal separator $S$ such that $G[S]$ is not complete multipartite. Thus, there exists $S_{0}=\{x, y, z\} \subseteq S$ that induces a $\overline{P_{3}}$
subgraph, say with edge $x y$ and isolated vertex $z$. Let $\tau_{1}$ and $\tau_{2}$ be $x$-to- $y$ paths with $\tau_{1}^{\circ}$ and $\tau_{2}^{\circ}$, respectively, inside distinct components $G_{1}$ and $G_{2}$ of $G-S$, and let $C$ be the cycle $\tau_{1} \cup \tau_{2}$. Let $\pi$ be a chordless $\tau_{1}^{\circ}$-to- $\tau_{2}^{\circ}$ path through $z$ with endpoints $u$ and $w$ and with $\pi^{\circ} \cap V(C)=\emptyset$. If $\pi_{1}$ and $\pi_{2}$ are the two $u$-to- $w$ subpaths of $C$ and $\pi_{3}=\pi$, then $S_{0}$ is a transversal of $\Theta\left(u, w ; \pi_{1}, \pi_{2}, \pi_{3}\right)$ of $G$. But then $G\left[S_{0}\right] \cong \overline{P_{3}}$, and yet, since $S$ is a minimal separator of $G$, the transversal $S_{0}$ is not crossed by a chord of $\Theta$.

Although it follows directly from the $\overline{P_{3}}$-free characterization of complete multipartite graphs in the final paragraph of Section 1, Theorem 2 fails to display how unichord-free graphs and chordal graphs are the fundamental special cases of the class of complete-multipartite-separator graphs. Theorems 3 and 5 will do this by introducing parameters that stratify this class so that unichord-free graphs and chordal graphs are the parameter-1 cases. Finally, Theorems 7 and 10 will characterize a new graph class that is the conjunction of the parameter- 2 cases.

## 3. When Each $G[S]$ Is Independent or is Complete

Motivated by theta graphs (which are sometimes called "3-skeins"), define a generalized $k$-skein $\Theta=\Theta\left(T_{1}, T_{2} ; \pi_{1}, \ldots, \pi_{k}\right)$ of $G$ to consist of disjoint subtrees $T_{1}$ and $T_{2}$ of $G$ with no vertex of $T_{1}$ adjacent to a vertex of $T_{2}$ together with $k \geq 2$ internally-disjoint, chordless $T_{1}$-to- $T_{2}$ paths $\pi_{1}, \ldots, \pi_{k}$ such that each $\pi_{i}^{\circ} \neq \emptyset$, each leaf of each $T_{i}$ is the endpoint of at least two of the paths $\pi_{1}, \ldots, \pi_{k}$, and no $v \in V\left(T_{1}\right) \cup V\left(T_{2}\right)$ is adjacent to any internal vertex of any of $\pi_{1}, \ldots, \pi_{k}$ except when $v$ is an endpoint of such a path. (The subtrees $T_{1}$ and $T_{2}$ are not necessarily induced subgraphs of $G$, and an endpoint of $\pi_{i}$ does not have to be a leaf of $T_{1}$ or $T_{2}$.) Theta graphs are generalized 3-skeins with $V\left(T_{1}\right)=\{u\}$ and $V\left(T_{2}\right)=\{w\}$, and a cycle $C$ with nonconsecutive vertices $u$ and $w$ is a generalized 2-skein with $V\left(T_{1}\right)=\{u\}$ and $V\left(T_{2}\right)=\{w\}$ where $C=\pi_{1} \cup \pi_{2}$.

Define a chord of $\Theta=\Theta\left(T_{1}, T_{2} ; \pi_{1}, \ldots, \pi_{k}\right)$ to be an edge with endpoints in each of $\pi_{i}^{\circ}$ and $\pi_{j}^{\circ}$ where $i \neq j$, and define a transversal of $\Theta$ to be any set $\left\{z_{1}, \ldots, z_{k}\right\}$ where each $z_{i} \in \pi_{i}^{\circ}$; thus $\left\{z_{1}, \ldots, z_{k}\right\}$ is a minimal separator of $\Theta$ (but not necessarily of $G[V(\Theta)]$, because chords of $\Theta$ will be edges of $G[V(\Theta)]$ ). Say that a transversal $\left\{z_{1}, \ldots, z_{k}\right\}$ of $\Theta$ is crossed by a chord of $\Theta$ if some chord $x y$ of $\Theta$ has $x$ an internal vertex of the $T_{1}$-to- $z_{i}$ subpath of $\pi_{i}$ and $y$ an internal vertex of the $z_{j}$-to- $T_{2}$ subpath of $\pi_{j} \neq \pi_{i}$.

A simple result from [4] is that a graph is unichord-free if and only if every chord $x y$ of every cycle $C$ has $\{x, y\}$ crossed by a chord of $C$. This characterization will be the $p=1$ case of Theorem 3, in Corollary 4.

The clique number $\omega=\omega(G)$ of a graph $G$ is the largest order of a complete subgraph of $G$. Thus, for each $p \geq 1$, saying that a complete multipartite graph
$G$ has clique number $\omega \leq p$ in Theorem 3 is equivalent to saying that $G$ is complete $k$-partite for some $k \leq p$ (which happens to be how complete $p$-partite graphs would be defined if the partite sets $V_{1}, \ldots, V_{p-1}$ had been allowed to be empty). Thus, $G$ is complete multipartite with clique number $\omega \leq p$ if and only if $G$ is $\overline{P_{3}}$-free (to ensure $G$ is complete multipartite) and $K_{p+1}$-free (to ensure $\omega(G) \leq p)$.

Theorem 3. Suppose $G$ is a complete-multipartite-separator graph. Every minimal separator of $G$ induces a complete multipartite subgraph with clique number $\omega \leq p$ if and only if, for every generalized $(p+1)$-skein $\Theta$ with transversal $S$, if $G[S] \cong K_{p+1}$, then $S$ is crossed by a chord of $\Theta$.

Proof. First, suppose every minimal separator of $G$ induces a complete multipartite subgraph with clique number $\omega \leq p$ and $\Theta=\Theta\left(T_{1}, T_{2} ; \pi_{1}, \ldots, \pi_{p+1}\right)$ is a generalized $(p+1)$-skein of $G$ with transversal $S=\left\{z_{1}, \ldots, z_{k}\right\}$ where $G[S] \cong K_{p+1}$. Since $K_{p+1}$ has clique number $\omega>p$, the transversal $S$ cannot be contained in a minimal separator of $G[V(\Theta)]$ by Lemma 1. Therefore, $S$ is crossed by a chord of $\Theta$ (since each $\pi_{i}$ is chordless and no vertex of $T_{1}$ is adjacent in $G$ to a vertex of $T_{2}$ ).

Conversely, suppose $G$ is a complete-multipartite-separator graph with a minimal separator $S^{\prime}$ such that $G\left[S^{\prime}\right]$ has clique number $\omega>p \geq 1$, say with $S=\left\{z_{1}, \ldots, z_{p+1}\right\} \subseteq S^{\prime}$ where $G[S] \cong K_{p+1}$. Let $\sigma$ and $\tau$ be $z_{1}$-to- $z_{2}$ paths with $\sigma^{\circ}$ and $\tau^{\circ}$, respectively, inside distinct components $G[U]$ and $G[W]$ of $G-S^{\prime}$ such that each $z_{i} \in S$ has neighbors in both $U$ and $W$.

Let $C$ be the cycle $\sigma \cup \tau$ with $u_{1} \in \sigma^{\circ}$ and $w_{1} \in \tau^{\circ}$, and let $\pi_{1}^{\prime}$ and $\pi_{2}^{\prime}$ be the $u_{1}$-to- $w_{1}$ subpaths of $C$ through, respectively, $z_{1}$ and $z_{2}$. Let $\Pi_{2}=\pi_{1} \cup \pi_{2}$ and let $\pi_{3}$ be a chordless $u_{2}$-to- $w_{2}$ path where $u_{2} \in U$ and $w_{2} \in W$ are both vertices of $\Pi_{2}$ such that $\pi_{3}^{\circ} \cap S^{\prime}=\left\{z_{3}\right\}$ and $\pi_{3}^{\circ} \cap V\left(\Pi_{2}\right)=\emptyset$. Let $T_{1}$ be the trivial subtree $u_{2}$ of $G[U]$, let $T_{2}$ be the trivial subtree $w_{2}$ of $G[W]$, and let $\pi_{1}$ and $\pi_{2}$ be the $u_{2}$-to- $w_{2}$ paths of $\Pi_{2}$. This makes $\Theta\left(u_{2}, w_{2} ; \pi_{1}, \pi_{2}, \pi_{3}\right)$ a theta graph and $\Theta\left(T_{1}, T_{2} ; \pi_{1}, \pi_{2}, \pi_{3}\right)$ a generalized 3 -skein.

For $3 \leq i \leq p$, continue recursively by letting $\Pi_{i}=\pi_{1} \cup \cdots \cup \pi_{i}$ and letting $\pi_{i+1}$ be a chordless $u_{i}$-to- $w_{i}$ path where $u_{i} \in U$ and $w_{i} \in W$ are vertices of $\Pi_{i}$ such that $\pi_{i+1}^{\circ} \cap S^{\prime}=\left\{z_{i+1}\right\}$ and $\pi_{i+1}^{\circ} \cap V\left(\Pi_{i}\right)=\emptyset$. Enlarge $T_{1}$ to become a minimal subtree of $G[U] \cap \Pi_{i}$ that contains $\left\{u_{2}, \ldots, u_{i}\right\}$, and enlarge $T_{2}$ to become a minimal subtree of $G[W] \cap \Pi_{i}$ that contains $\left\{w_{2}, \ldots, w_{i}\right\}$. This makes $\Theta\left(T_{1}, T_{2} ; \pi_{1}, \pi_{2}, \ldots, \pi_{i+1}\right)$ a generalized $(i+1)$-skein.

This process ends with a generalized $(p+1)$-skein $\Theta=\Theta\left(T_{1}, T_{2} ; \pi_{1}, \ldots\right.$, $\pi_{p+1}$ ), with $z_{i} \in \pi_{i}^{\circ}$ whenever $1 \leq i \leq p+1$, such that $\Theta$ has transversal $S$. But then $G[S] \cong K_{p+1}$ and yet $S$ is not crossed by a chord of $\Theta$ (since $S^{\prime}$ is a minimal separator of $G$ with $T_{1}$ and $T_{2}$ in, respectively, the components $G[U]$ and $G[W]$ of $G-S^{\prime}$ ).

Corollary 4. A graph is unichord-free if and only if every chord $x y$ in every cycle $C$ has $\{x, y\}$ crossed by a chord of $C$.

Proof. Recall that $G$ is unichord-free if and only if every minimal separator induces an edgeless subgraph (a complete multipartite subgraph with clique number $\omega=1$ ). The "only if" direction follows from a cycle $C$ with a chord $x y$ corresponding to a generalized 2-skein with each $\left|V\left(T_{i}\right)\right|=1$ of which $S=\{x, y\}$ is a transversal (with $G[S] \cong P_{2}$ ). Therefore, by the $p=1$ case of Theorem 3, $S=\{x, y\}$ is crossed by a chord of $C$.

For the "if" direction, a graph that is not unichord-free has a cycle $C$ with a unique chord $x y$, where $C$ corresponds to a generalized 2 -skein $\Theta$ with transversal $S=\{x, y\}$ that has $G[S] \cong P_{2}$, and yet $S$ is not crossed by a chord of $\Theta$.

Now consider chordal graphs, at the other extreme of complete multipartite graphs from unichord-free graphs. A simple inductive argument on the length of cycles show that a graph is chordal if and only if every two nonadjacent vertices $x$ and $y$ of every cycle $C$ has $\{x, y\}$ crossed by a chord of $C$. This characterization will be the $q=1$ case of Theorem 5 , in Corollary 6.

The independence number $\alpha=\alpha(G)$ of a graph $G$ is the largest order of an edgeless induced subgraph of $G$. Thus, $G$ is complete multipartite graph with independence number $\alpha \leq q$ if and only if $G$ is $\overline{P_{3}}$-free (to ensure $G$ is complete multipartite) and $\overline{K_{q+1}}$-free (to ensure $\alpha(G) \leq q$ ).

Theorem 5. Suppose $G$ is a complete-multipartite-separator graph. Every minimal separator of $G$ induces a complete multipartite subgraph with independence number $\alpha \leq q$ if and only if, for every generalized $(q+1)$-skein $\Theta$ with transversal $S$, if $G[S] \cong \overline{K_{q+1}}$, then $S$ is crossed by a chord of $\Theta$.

Proof. This follows by the same proof as Theorem 3, replacing mentions of clique number with independence number, $p$ with $q$, and $K_{p+1}$ with $\overline{K_{q+1}}$.

Corollary 6. A graph is chordal if and only if every two nonadjacent vertices $x$ and $y$ of every cycle $C$ has $\{x, y\}$ crossed by a chord of $C$.

Proof. Recall that $G$ is chordal if and only if every minimal separator induces a complete subgraph (a complete multipartite graph with independence number $\alpha=1$ ). The "only if" direction follows as in the proof of Corollary 4, except now $G[S] \cong \overline{P_{2}}$ and the $q=1$ case of Theorem 5 is used.

For the "if" direction, a graph that is not chordal has a chordless cycle $C$ of length at least 4 , where $C$ corresponds to a generalized 2-skein $\Theta$ with (each) transversal $S=\{x, y\}$ that has $G[S] \cong \overline{P_{2}}$, and yet $S$ is not crossed by a chord of $\Theta$.

As an easy joint consequence of the $p=1$ and $q=1$ cases of Theorems 3 and 5 , a graph $G$ is simultaneously unichord-free and chordal if and only if, for every two nonconsecutive vertices $x$ and $y$ (adjacent or not) of every cycle $C$ of $G$, there is a chord that crosses $\{x, y\}$-in other words, every pair of vertices of $C$ that might be crossed by a chord of $C$ is crossed by a chord of $C$. The following two conditions are trivially equivalent to that characterization:
(C1) Every 2-connected subgraph of $G$ is complete (such a $G$ is often called a block graph).
(C2) Every minimal separator of $G$ is a singleton.
Section 4 will consider a more interesting joint consequence of Theorems 3 and 5 , except now of the $p=2$ and $q=2$ cases.

## 4. When Each $G[S]$ is an Induced Subgraph of $C_{4}$

Define an induced-sub-C4-separator graph to be a graph $G$ in which every minimal separator $S$ of $G$ induces a graph $H$ that is isomorphic to an induced subgraph of $C_{4} \cong K(2,2)$-equivalently, $H$ is one of the five graphs in Figure 1. It is simple to check that $H$ being an induced subgraph of $C_{4}$ is also equivalent to every three vertices of $H$ inducing a path; or, alternatively, to $H$ being simultaneously $\overline{P_{3}}$-free, $K_{3}$-free, and $\overline{K_{3}}$-free. Theorems 7 and 10 will characterize the induced-sub- $C_{4}$-separator graphs (with the $G[S] \cong \overline{P_{3}}$ condition of Theorem 2 becoming $G[S] \not \not \neq P_{3}$ in clause (2) of Theorem 7).

Figure 1. The five induced subgraphs of the complete bipartite graph $C_{4}$.
Theorem 7. Each of the following is equivalent to a graph $G$ being an induced-sub-C4-separator graph:
(1) Every minimal separator of $G$ induces a complete multipartite subgraph with clique number $\omega \leq 2$ and independence number $\alpha \leq 2$.
(2) $G$ is a complete-multipartite-separator graph and, for every theta subgraph $\Theta$ of $G$ with transversal $S$, if $G[S] \not \not P_{3}$, then $S$ is crossed by a chord of $\Theta$.
Proof. The equivalence with (1) follows from the graphs in Figure 1 being the complete multipartite graphs $K(1), K(1,1), K(2), K(1,2)$, and $K(2,2)$, which are the only complete multipartite graphs that have both $\alpha, \omega \leq 2$.

For the necessity of (2), suppose $G$ is an induced-sub- $C_{4}$-separator graph that contains a theta subgraph $\Theta$ with transversal $S$ (so $|S|=3$ ) such that $G[S] \not \approx P_{3}$. Theorem 2 implies $G[S] \not \approx \overline{P_{3}}$, and so $G[S]$ is isomorphic to $K_{3}$ or $\overline{K_{3}}$. Therefore, $S$ is crossed by a chord of $\Theta$ using, respectively, the $\omega=p=2$ case of Theorem 3 or the $\alpha=q=2$ case of Theorem 5 .

For the sufficiency of (2), suppose some minimal separator $R$ of $G$ has $G[R]$ that is not an induced subgraph of $C_{4}$. Thus $|R| \geq 3$ (since $K_{1}, K_{2}$, and $\overline{K_{2}}$ are induced subgraphs of $C_{4}$ ) and there exists an $S=\{x, y, z\} \subseteq R$ with $G[S] \not \equiv P_{3}$. Let $\tau_{1}$ and $\tau_{2}$ be $x$-to- $y$ paths with $\tau_{1}^{\circ}$ and $\tau_{2}^{\circ}$ inside different components of $G-R$, let $\pi_{3}$ be a chordless $\tau_{1}^{\circ}$-to- $\tau_{2}^{\circ}$ path through $z$ with $\pi_{3}^{\circ} \cap V\left(\tau_{1} \cup \tau_{2}\right)=\emptyset$ (using that $R$ is a minimal separator of $G$ ), let $u$ and $w$ be the endpoints of $\pi_{3}$, and let $\pi_{1}$ and $\pi_{2}$ be the two $u$-to- $w$ subpaths of $\tau_{1} \cup \tau_{2}$. Thus $S$ is a transversal of the theta subgraph $\Theta\left(u, w ; \pi_{1}, \pi_{2}, \pi_{3}\right)$ of $G$ and $G[S] \not \not P_{3}$, and yet $S$ is not crossed by a chord of $\Theta$ (since $R$ is a minimal separator of $G$ ).

Lemma 8 will characterize the 3 -connected induced-sub- $C_{4}$-separator graphs in the style of condition ( C 1 ) at the end of Section 3. A wheel graph consists of a chordless cycle and a vertex that is adjacent to every vertex of that cycle.

Lemma 8. A 3-connected graph is an induced-sub-C $C_{4}$-separator graph if and only if it is either complete, a wheel, or the octahedron $K(2,2,2)$.

Proof. First, suppose $G$ is a 3-connected induced-sub- $C_{4}$-separator graph. Thus, every minimal separator $S$ of $G$ has $|S| \geq 3$ and so induces a $P_{3}$ or $C_{4}$ subgraph. Also suppose $G$ is not complete.

Case 1. $S=\{a, b, c\}$ is a minimal separator of $G$ with $G[S] \cong P_{3}$ having the edges $a b$ and $b c$. Let $G_{1}$ and $G_{2}$ be components of $G-S$ such that every vertex of $S$ has a neighbor in each of them, and let $\tau_{1}$ and $\tau_{2}$ be chordless $a$-to- $c$ paths with each $\tau_{i}^{\circ}$ in $G_{i}$. Say $\tau_{1}=v_{0}, v_{1}, v_{2}, \ldots, v_{t}$ with $v_{0}=a$ and $v_{t}=c$ has length $t \geq 2$, and let $a^{\prime}$ be the neighbor of $a$ in $\tau_{2}$. If $t \geq 3$, then $\tau_{1}^{\circ} \subset N(b)$ (to prevent, when $1 \leq j \leq t-1$, either $\left\{a, b, v_{j}\right\}$ being in a minimal $c, v_{j-1}$-separator of $G\left[S \cup \tau_{1}^{\circ} \cup \tau_{2}^{\circ}\right]$ or $\left\{b, c, v_{j}\right\}$ being in a minimal $a, v_{j+1}$-separator of $G\left[S \cup \tau_{1}^{\circ} \cup \tau_{2}^{\circ}\right]$, either of which would, by Lemma 1, be in a minimal separator of $G$ and induce a $\overline{P_{3}}$ subgraph of $G$ ). If, instead, $t=2$, then $\tau_{1}^{\circ} \subset N(b)$ (to prevent $\left\{b, v_{1}, a^{\prime}\right\}$ from being a minimal $a, c$-separator of $G\left[S \cup \tau_{1}^{\circ} \cup \tau_{2}^{\circ}\right]$ that would, by Lemma 1, be in a minimal separator of $G$ and induce a $\overline{P_{3}}$ or a $\overline{K_{3}}$ subgraph of $G$, depending on whether or not $a^{\prime}$ is adjacent to $b$ ). Either way, $\tau_{1}^{\circ} \subset N(b)$ and, similarly, $\tau_{2}^{\circ} \subset N(b)$. Therefore, $S$ is in the wheel $H_{S}=G\left[S \cup \tau_{1}^{\circ} \cup \tau_{2}^{\circ}\right]$, centered at $b$.

If $G-S$ has a third component $G_{3}$, then $G$ being 3-connected ensures there exists a chordless $a$-to- $c$ path $\tau_{3}$ with $\tau_{3}^{\circ}$ in $G_{3}$, and so $\tau_{3}^{\circ} \subset N(b)$ (as in the preceding paragraph) and $x_{1}, x_{2}, x_{3} \in N(a)$ with each $x_{i} \in \tau_{i}^{\circ}$ would form a minimal $a, c$-separator of $G\left[\tau_{1} \cup \tau_{2} \cup \tau_{3}\right]$ that would, by Lemma 1 , be in a minimal
separator of $G$ and induce a $\overline{K_{3}}$ subgraph of $G$. Therefore, $G-S$ has only the two components $G_{1}$ and $G_{2}$.

If $G \neq H_{S}$, then there exists $z \in V(G)-V\left(H_{S}\right)$, say with $z \in V\left(G_{1}\right)-\tau_{1}^{\circ}$. Form a new graph $G^{+}$by appending one new vertex $\nu$ to $G$ such that $N(\nu)=$ $V\left(\tau_{1}\right)$. Since $G^{+}$is also 3 -connected, Menger's Theorem ensures that $G^{+}$has three internally-disjoint $\nu$-to- $z$ paths that intersect $\tau_{1}$ at three vertices in a minimal $\nu, z$ separator $S^{\prime}$ of $G^{+}$; moreover, since $\left|S^{\prime}\right| \geq 3$, at least one of these three vertices, say $v_{i}$, is in $\tau_{1}^{\circ}$. But then vertices $a^{\prime}, v_{i}$, and $b$ would be internal vertices of, respectively, the $a$-to- $c$ paths $\tau_{1}, \tau_{2}$, and the length- 2 path $a, b, c$, along with $z$ being an internal vertex of an additional $a$-to- $c$ path with internal vertices in $G_{1}$ (using that $G$ is 3 -connected). Thus $\left\{a^{\prime}, b, v_{i}, z\right\}$ would be in a minimal $a, c$ separator of $G$ that does not induce a $C_{4}$ subgraph. Therefore, $G$ is the wheel $H_{S}$.

Case 2. $S=\{a, b, c, d\}$ is a minimal separator of $G$ with $G[S] \cong C_{4}$ having the edges $a b, b c, c d$, and $a d$. Let $G_{1}$ and $G_{2}$ be components of $G-S$ such that every vertex of $S$ has a neighbor in each of them, and let $\tau_{1}$ and $\tau_{2}$ be chordless $a$-to- $c$ paths with each $\tau_{i}^{\circ}$ in $G_{i}$. As in the argument for Case $1, \tau_{1}^{\circ} \subset N(b)$ (using $\left.G[\{a, b, c\}] \cong P_{3}\right)$ and $\tau_{1}^{\circ} \subset N(d)\left(\right.$ using $\left.G[\{a, d, c\}] \cong P_{3}\right)$. Pick any $x_{1} \in \tau_{1}^{\circ}$ and let $\tau_{1}^{\prime}$ be the $b$-to- $d$ path $b, x_{1}, d$ in $G_{1}$. As in the argument for Case 1, $\left(\tau_{1}^{\prime}\right)^{\circ} \in N(c)\left(\right.$ using $\left.G[\{b, c, d\}] \cong P_{3}\right)$ and $\left(\tau_{1}^{\prime}\right)^{\circ} \subset N(a)\left(u \operatorname{sing} G[\{b, a, d\}] \cong P_{3}\right)$. Thus $S \subseteq N\left(x_{1}\right)$, and similarly $S \subseteq N\left(x_{2}\right)$ for some $x_{2}$ in $G_{2}$. Therefore, $S$ is in the octahedron $H_{S}=G\left[S \cup\left\{x_{1}, x_{2}\right\}\right]$.

If $G-S$ has a third component $G_{3}$, then $G$ being 3-connected ensures there exists a chordless $a$-to-c or $b$-to- $d$ path $\tau_{3}$ with $\tau_{3}^{\circ}$ in $G_{3}$; without loss of generality, say $\tau_{3}$ is an $a$-to- $c$ path. Thus, as in Case $1, x_{1}, x_{2}$ and any $x_{3} \in \tau_{3}^{\circ}$ would form a minimal $a, c$-separator of $G\left[\tau_{1}^{\circ} \cup \tau_{2}^{\circ} \cup \tau_{3}^{\circ}\right]$ that would induce a $\overline{K_{3}}$ subgraph of $G$. Therefore, $G-S$ has only the two components $G_{1}$ and $G_{2}$.

If $G \neq H_{S}$, then there exists $z \in V(G)-V\left(H_{S}\right)$, say with $z \in V\left(G_{1}\right)-\left\{x_{1}\right\}$. Since $G$ is 3-connected, Menger's Theorem requires $G$ to have three internallydisjoint $z$-to- $x_{2}$ paths that intersect $S$ at three vertices in a minimal $z, x_{2}$-separator of $G$; without loss of generality, say these three vertices of $S$ are $a, b, c$. But then vertices $x_{1}, x_{2}$, and $b$ would be internal vertices of, respectively, the length- $2 a$-to- $c$ paths $a, x_{1}, c$ and $a, x_{2}, b$ and $a, b, c$, along with $z$ being an internal vertex of an additional $a$-to- $c$ path with internal vertices in $G_{1}$ (using that $G$ is 3 -connected). Thus $\left\{b, x_{1}, x_{2}, z\right\}$ would be in a minimal $a, c$-separator of $G$ that does not induce a $C_{4}$ subgraph. Therefore, $G$ is the octahedron $H_{S}$.

Conversely, complete graphs have no minimal separators at all, and each minimal separator of a wheel or octahedron induces, respectively, a $P_{3}$ or $C_{4}$ subgraph.
Lemma 9. A 2-connected graph in which no minimal separator induces a $K_{2}$ subgraph is an induced-sub-C $C_{4}$-separator graph if and only if it is either complete, a cycle, a wheel, or the octahedron.

Proof. First, suppose $G$ is a 2-connected induced-sub- $C_{4}$-separator graph in which no minimal separator induces a $K_{2}$ subgraph. If $G$ is 3 -connected, then $G$ is either complete, a wheel, or the octahedron by Lemma 8.

Hence, assume $G$ is not complete and has a minimal separator $S=\{a, b\}$ with $G[S] \cong \overline{K_{2}}$. Since a minimal $a, b$-separator of $G$ must be one of the graphs in Figure 1 and cannot be $K_{1}$ (using that $G$ is 2 -connected) or any of $K_{2}, P_{3}$ or $C_{4}$ (using that $S$ is a minimal separator of $G$ ), every minimal $a, b$-separator of $G$ must induce a $\overline{K_{2}}$ subgraph of $G$ where $G-S$ has exactly two components $G_{1}$ and $G_{2}$ and each minimal $a, b$-separator of each subgraph $G_{i}^{+}=G\left[V\left(G_{i}\right) \cup S\right]$ is a singleton. Since no minimal separator of $G$ induces a $K_{1}$ or $K_{2}$ subgraph, $G_{1}^{+}$ and $G_{2}^{+}$are internally-disjoint $a$-to- $b$ paths. Therefore, $G$ is a cycle.

Conversely, each minimal separator of a cycle induces a $\overline{K_{2}}$ subgraph, and the minimal separators of complete graphs, wheels, and the octahedron are covered by Lemma 8 .

In Theorem 10, the 2-clique-sum of vertex-disjoint graphs $H_{1}$ and $H_{2}$ results from identifying a clique of order at most 2 from each of $H_{1}$ and $H_{2}$ (in other words, identifying an edge of $H_{1}$ with an edge of $H_{2}$, or a vertex of $H_{1}$ with a vertex of $H_{2}$ ).

Theorem 10. A graph is an induced-sub-C4-separator graph if and only if it can be built from complete graphs, cycles, octahedra, and wheels by repeatedly forming 2 -clique-sums.

Proof. This follows from Lemma 9.
