#### Abstract

A dominating set in a graph $G$ is a set $S$ of vertices such that every vertex in $V(G) \backslash S$ is adjacent to at least one vertex in $S$, and the domination number of $G$ is the minimum cardinality of a dominating set of $G$. Placing constraints on a dominating set yields different domination parameters, including total, connected, restrained, and clique domination numbers. In this paper, we study relationships among domination parameters of a graph and its complement.

Keywords: domination, complement, total domination, connected domination, clique domination, restrained domination.
2010 Mathematics Subject Classification: 05C69.

## 1. InTRODUCTION

The literature on the subject of domination parameters in graphs has been surveyed through 1997 and detailed in the two books [7, 8]. Our aim in this paper
is to study graph relationships involving domination parameters in a graph $G$ and its complement $\bar{G}$. We will also study relationships between the domination number of a graph and its total, restrained, clique and connected domination numbers.

For notation and graph theory terminology not defined herein, we refer the reader to [7]. Let $G=(V, E)$ be a graph with vertex set $V=V(G)$ of order $n=$ $|V|$ and edge set $E=E(G)$ of size $m=|E|$, and let $v$ be a vertex in $V$. The open neighborhood of $v$ is $N_{G}(v)=\{u \in V \mid u v \in E\}$, and the closed neighborhood of $v$ is $N_{G}[v]=\{v\} \cup N_{G}(v)$. We denote the complement of a graph $G$ by $\bar{G}$. For any vertex $v$, we call the subgraph of $G$ induced by $N_{G}(v)$ the link of $v$ and will denote it as $\mathcal{L}(v)$. We will denote the subgraph of $\bar{G}$ induced by $N_{G}(v)$ as $\overline{\mathcal{L}}(v)$. For a set $S \subseteq V$, its open neighborhood is the set $N_{G}(S)=\bigcup_{v \in S} N(v)$, and its closed neighborhood is the set $N_{G}[S]=N_{G}(S) \cup S$. The degree of a vertex $v$ in $G$ is $d_{G}(v)=\left|N_{G}(v)\right|$. If the graph $G$ is clear from the context, we simply write $d(v), N(v), N[v], N(S)$ and $N[S]$ rather than $d_{G}(v), N_{G}(v), N_{G}[v], N_{G}(S)$ and $N_{G}[S]$, respectively. A vertex is isolated in $G$ if its degree in $G$ is zero. A graph is isolate-free if it has no isolated vertex. For any set $S \subset V(G)$, we denote the subgraph induced by $S$ as $G[S]$. The minimum and maximum degree among the vertices of $G$ is denoted by $\delta(G)$ and $\Delta(G)$, respectively. For a subset $X \subseteq V$, the degree of a vertex $v$ in $X$, denoted $d_{X}(v)$, is the number of vertices in $X$ adjacent to $v$; that is, $d_{X}(v)=|N(v) \cap X|$. In particular, $d_{G}(v)=d_{V}(v)$.

For sets $A, B \subseteq V$, we let $G[A, B]$, or simply $[A, B]$ if the graph is clear from the context, denote the set of edges in $G$ with one end in $A$ and the other in $B$. A nontrivial graph is a graph with at least two vertices. We say that a graph is $F$-free if it does not contain $F$ as an induced subgraph. In particular, if $F=K_{1,3}$, then we say that the graph is claw-free.

A dominating set in $G=(V, E)$ is a set $S$ of vertices of $G$ such that every vertex in $V \backslash S$ is adjacent to at least one vertex in $S$, that is, $N[S]=V$. The domination number of $G$, denoted by $\gamma(G)$, is the minimum cardinality of a dominating set of $G$. A dominating set of $G$ of cardinality $\gamma(G)$ is called a $\gamma(G)$ set. For subsets $X, Y \subseteq V$, the set $X$ dominates the set $Y$ in $G$ if $Y \subseteq N[X]$. In particular, if $X$ dominates $V$, then $X$ is a dominating set of $G$. A vertex is called $\gamma(G)$-good if it is contained in some $\gamma(G)$-set, and $\gamma(G)$-bad, otherwise. In other words, a $\gamma(G)$-good vertex is contained in at least one $\gamma(G)$-set, while a $\gamma(G)$ bad vertex is not in any $\gamma(G)$-set. The minimum degree among the $\gamma(G)$-good (respectively, $\gamma(G)$-bad) vertices of $G$ is denoted by $\delta_{g}(G)$ (respectively, $\delta_{b}(G)$ ).

A total dominating set, abbreviated TD-set, of $G$ is a set $S$ of vertices of $G$ such that every vertex in $V(G)$ is adjacent to at least one vertex in $S$. The total domination number of $G$, denoted by $\gamma_{t}(G)$, is the minimum cardinality of a TD-set of $G$. A TD-set of $G$ of cardinality $\gamma_{t}(G)$ is called a $\gamma_{t}(G)$-set. Total domination is now well studied in graph theory. The literature on the subject of
total domination in graphs has been surveyed and detailed in the recent book [10]. A survey of total domination in graphs can also be found in [9].

Another way of looking at total domination is that a dominating set $S$ is a TD-set if the induced subgraph $G[S]$ has no isolated vertices. Placing the constraint that $G[S]$ is connected (respectively, a complete graph) yields connected domination (respectively, clique domination). More formally, a dominating set $S$ is a connected dominating set, abbreviated CD-set, of a graph $G$ if the induced subgraph $G[S]$ is connected. Every connected graph has a CD-set, since $V$ is such a set. The connected domination number of $G$, denoted by $\gamma_{c}(G)$, is the minimum cardinality of a CD-set of $G$, and a CD-set of $G$ of cardinality $\gamma_{c}(G)$ is called a $\gamma_{c}(G)$-set. Connected domination in graphs was first introduced by Sampathkumar et al. [14] and is now very well studied (see, for example, [4] and the recent papers $[13,15])$. The study of connected domination has extensive application in the study of routing problems and virtual backbone based routing in wireless networks $[6,12,17]$. A subset $S \subset V$ of vertices in a graph $G=(V, E)$ is a dominating clique in $G$ if $S$ dominates $V$ in $G$ and $G[S]$ is complete. If a graph $G$ has a dominating clique, then the minimum cardinality among all dominating cliques of $G$ is the clique domination number of $G$, denoted by $\gamma_{\mathrm{cl}}(G)$.

A restrained dominating set of a graph $G$ is a set $S$ of vertices in $G$ such that every vertex in $V \backslash S$ is adjacent to a vertex in $S$ and to some other vertex in $V \backslash S$. Every connected graph has an RD-set, since $V$ is such a set. The restrained domination number of $G$, denoted by $\gamma_{r}(G)$, is the minimum cardinality of an RD-set of $G$, and an RD-set of $G$ of cardinality $\gamma_{r}(G)$ is called a $\gamma_{r}(G)$-set.

A proper vertex coloring of a graph $G$ is an assignment of colors (elements of some set) to the vertices of $G$, one color to each vertex, so that adjacent vertices are assigned distinct colors. If $k$ colors are used, then the coloring is referred to as a $k$-coloring. In a given coloring of $G$, a color class of the coloring is a set consisting of all those vertices assigned the same color. The vertex chromatic number $\chi(G)$ of $G$ is the minimum integer $k$ such that $G$ is $k$-colorable. A $\chi(G)$ coloring of $G$ is a coloring of $G$ with $\chi(G)$ colors.

Given a graph $G$, two edges are said to cross in the plane if in a drawing of the graph in the plane they intersect at a point that is not a vertex. The graph $G$ is planar if it can be drawn in the plane with no edges crossing. The crossing number of $G$, denoted $\operatorname{cr}(G)$, is the minimum number of crossing edges amongst all drawings of $G$ in the plane. Note that if $G$ is planar, then necessarily $c r(G)=0$.

## 2. Bounds on the Domination Number

In this section, we determine bounds on the domination number. If the graph $G$ is clear from the context, then we write $\delta, \bar{\delta}, \Delta, \bar{\Delta}, \gamma$ and $\bar{\gamma}$ rather than $\delta(G)$,
$\delta(\bar{G}), \Delta(G), \Delta(\bar{G}), \gamma(G)$ and $\gamma(\bar{G})$, respectively.

### 2.1. Dominating the complement of a graph

We begin with results bounding the domination number of the complement of a graph. If $v$ is an arbitrary vertex in a graph $G$, then the closed neighborhood, $N_{G}[v]$, of $v$ is a dominating set of $\bar{G}$. In particular, choosing $v$ to be a vertex of minimum degree in $G$, we have that $\gamma(\bar{G}) \leq \delta(G)+1$. Furthermore, a set formed by taking a vertex from each color class of an arbitrary $\chi(G)$-coloring of $G$ is a dominating set of $\bar{G}$, and so $\gamma(\bar{G}) \leq \chi(G)$. We state these well known observations formally as follows.
Observation 1. Let $G$ be a graph. Then the following hold
(a) $\gamma(\bar{G}) \leq \delta(G)+1$.
(b) $\gamma(\bar{G}) \leq \chi(G)$.

By Observation 1, $\gamma(\bar{G}) \leq \Delta(G)+1$. From Brook's Coloring Theorem [2], $\chi(G) \leq \Delta(G)+1$ with equality if and only if $G$ is the complete graph or an odd cycle. Noting that the domination number of the complement of any odd cycle $C_{n}$, where $n \geq 5$, is equal to 2 , we observe that if $G$ is a graph, then $\gamma(\bar{G}) \leq \Delta(G)+1$ with equality if and only if $G$ is a complete graph. Next we give an upper bound on $\gamma(\bar{G})$ in terms of $\gamma(G)$ and $\delta(G)$.
Theorem 2. If $G$ is a graph with $\gamma(G) \geq 2$, then $\gamma(\bar{G}) \leq\left\lceil\frac{\delta(G)}{\gamma(G)-1}\right\rceil+1$.
Proof. Let $v$ be a vertex of $G$ having degree $\delta$. Let $A=N_{G}(v)$, and so $|A|=\delta$. Let $k=\lceil\delta /(\gamma-1)\rceil$ and partition the set $A$ into $k$ sets $A_{1}, \ldots, A_{k}$ each of cardinality at most $\gamma-1$. Thus, $A=\bigcup_{i=1}^{k} A_{i}$ and $1 \leq\left|A_{i}\right| \leq \gamma-1$ for each $i$, $1 \leq i \leq k$. In particular, we note that no set $A_{i}$ dominates $V$ in $G$. For each set $A_{i}, 1 \leq i \leq k$, select one vertex $a_{i} \in V \backslash A_{i}$ that is not dominated by $A_{i}$ in $G$, and let $A^{\prime}=\bigcup_{i=1}^{k}\left\{a_{i}\right\}$. Then, $\left|A^{\prime}\right| \leq k$ and $A^{\prime}$ dominates $A$ in $\bar{G}$. Therefore, the set $A^{\prime} \cup\{v\}$ is a dominating set of $\bar{G}$, and so $\bar{\gamma} \leq\left|A^{\prime}\right|+1 \leq k+1=1+\lceil\delta /(\gamma-1)\rceil$.

As an immediate consequence of Theorem 2, we have the following corollaries.
Corollary 1. If $G$ is a graph with $\gamma(\bar{G})>\gamma(G) \geq 2$, then $\delta(G) \geq \gamma(G)$.
The next result shows that if $G$ is a graph satisfying $\gamma(G) \geq \gamma(\bar{G})-1$, then the bound of Observation 1(a) can be improved.
Corollary 2. If $G$ is a graph satisfying $\gamma(G) \geq \gamma(\bar{G})-1$, then $\gamma(\bar{G})<2+\sqrt{\delta(G)}$.
Proof. Let $G$ be a graph satisfying $\gamma \geq \bar{\gamma}-1$. If $\gamma=1$, then $\bar{\gamma} \leq 2$, and the result follows. Accordingly, we may assume that $\gamma \geq 2$. By Theorem 2, $\bar{\gamma} \leq$ $\lceil\delta /(\gamma-1)\rceil+1$. This simplifies to $(\bar{\gamma}-2)(\gamma-1)<\delta$. By assumption, $\gamma \geq \bar{\gamma}-1$. Hence, $(\bar{\gamma}-2)(\bar{\gamma}-2)<\delta$, and the result follows.

From Corollary 2, we have the following Nordhaus-Gaddum type result for graphs $G$ with $\gamma(G)=\gamma(\bar{G})$.

Corollary 3. If $G$ is a graph with $\gamma(G)=\gamma(\bar{G})$, then $\gamma(G)+\gamma(\bar{G})<4+\sqrt{\delta(G)}+$ $\sqrt{\delta(\bar{G})}$.

### 2.2. Graphs $G$ with $\gamma(G)<\gamma(\overline{\boldsymbol{G}})$

For a subset $S \subset V$ in a graph $G=(V, E)$, let $X_{S}(G)$ be the set of all vertices $x$ in $V \backslash S$ such that $x$ dominates $S$ in $G$; that is, $X_{S}(G)=\{x \in V \backslash S \mid S \subseteq N(x)\}$. We observe that if $X_{S}(G)=\emptyset$, then $S$ is a dominating set of $\bar{G}$. We state this formally as follows.

Observation 3. If $G$ is a graph and $S \subset V$ satisfies $|S|<\gamma(\bar{G})$, then $X_{S}(G) \neq \emptyset$.
The following result establishes properties about the set $X_{S}(G)$.
Theorem 4. Let $G$ be a graph with $\gamma(\bar{G})=\gamma(G)+k$, where $k \geq 2$, and let $S$ be a $\gamma(G)$-set. It follows that $\left|X_{S}\right| \geq k$. Moreover, any subset $X^{\prime} \subseteq X_{S}$ of size $\left|X_{S}\right|-k+2$ is a dominating set of $G$.

Proof. By the definition of $X_{S}$, the set $S$ dominates $V \backslash\left(S \cup X_{S}\right)$ in $\bar{G}$. This gives that $S \cup X_{S}$ is a dominating set of $\bar{G}$, and so $\gamma(G)+\left|X_{S}\right|=|S|+\left|X_{S}\right| \geq$ $\gamma(\bar{G})=\gamma(G)+k$ which implies $\left|X_{S}\right| \geq k$.

Let $u$ be an arbitrary vertex in $V \backslash S$, and let $U=N_{G}(u) \cap X_{S}$. Since $S$ dominates $V \backslash\left(S \cup X_{S}\right)$ in $\bar{G}$, and $u$ dominates $X_{S} \backslash U$ in $\bar{G}$, the set $S \cup U \cup\{u\}$ is a dominating set of $\bar{G}$. Then, $\gamma(G)+k=\gamma(\bar{G}) \leq \gamma(G)+|U|+1$. Consequently, $k-1 \leq|U|=\left|N_{G}(u) \cap\left(X_{S} \backslash X^{\prime}\right)\right|+\left|N_{G}(u) \cap X^{\prime}\right| \leq k-2+\left|N_{G}(u) \cap X^{\prime}\right|$ and so $N_{G}(u) \cap X^{\prime} \neq \emptyset$. Hence, $X^{\prime}$ dominates $V \backslash S$ in $G$. Since every vertex of $X^{\prime}$ dominates $S$ in $G$, the set $X^{\prime}$ is a dominating set of $G$.

Let $G$ be a graph with $\gamma(G) \leq \gamma(\bar{G})-2$. Further, let $S$ be a $\gamma(G)$-set, and let $X=X_{S}(G)$. By definition of the set $X$, we note that the edges, $G[X, S]$, in $G$ between $X$ and $S$ induce a complete bipartite graph $K_{|X|,|S|}$. By Theorem 4, $\gamma \leq|X|$. Thus, we have the following corollary of Theorem 4.

Corollary 4. If $G$ is a graph with $\gamma(G) \leq \gamma(\bar{G})-2$, then $G$ contains $K_{\gamma, \gamma}$ as a subgraph.

We observe from Corollary 4 that if $G$ is a graph that contains no 4 -cycle (and thus does not contain $K_{r, r}$ for $r \geq 2$ as a subgraph), then $\gamma(G)=1$ or $\gamma(G) \geq \gamma(\bar{G})-1$. We establish next a property of claw-free graphs $G$ with $\gamma(G) \leq \gamma(\bar{G})-2$.

Theorem 5. Let $G$ be a graph with $\gamma(G) \leq \gamma(\bar{G})-2$, and let $S$ be a $\gamma(G)$-set. If $G$ is claw-free, then $\gamma(G) \leq 2$ or $S \cup X_{S}(G)$ is a clique in $G$.

Proof. Let $G=(V, E)$ be a claw-free graph with $\gamma \leq \bar{\gamma}-2$, and let $S$ be a $\gamma(G)$-set. Following our earlier notation, let $X=X_{S}(G)$. By Theorem 4, the set $X$ is a dominating set of $G$, and so $\gamma \leq|X|$. Suppose that $G[S \cup X]$ is not a clique. Then there are two vertices, say $a$ and $b$, in $S \cup X$ that are not adjacent in $G$. Since every vertex in $X$ is by definition adjacent in $G$ to every vertex in $S$, we observe that both $a$ and $b$ are in $S$ or both $a$ and $b$ are in $X$. Let $c$ be an arbitrary vertex in $V \backslash\{a, b\}$.

We show that $c$ is dominated by $\{a, b\}$. Suppose to the contrary that $c$ is adjacent to neither $a$ nor $b$. On the one hand, suppose that $\{a, b\} \subseteq S$. Then, $c \notin X$. However since $X$ is a dominating set in $G$, there is a vertex $x \in X$ that is adjacent to $c$ in $G$. But then the set $\{a, b, c, x\}$ induces a claw in $G$, a contradiction. On the other hand, suppose that $\{a, b\} \subseteq X$. Then, $c \notin S$. However since $S$ is a dominating set in $G$, there is a vertex $x \in S$ that is adjacent to $c$ in $G$. But then the set $\{a, b, c, x\}$ induces a claw in $G$, a contradiction. In both cases, we have that $c$ is dominated by $\{a, b\}$, implying that $\{a, b\}$ is a dominating set in $G$, and therefore, that $\gamma \leq 2$.

Let $G$ be a claw-free graph with $\gamma(G) \leq \gamma(\bar{G})-2$, and let $S$ be a $\gamma(G)$-set and let $X=X_{S}(G)$. If $\gamma(G) \geq 3$, then by Theorem 5 , the set $S \cup X$ is a clique in $G$, and therefore, an independent set in $\bar{G}$. Hence, as an immediate consequence of Theorem 5, we have the following result, where $\alpha(G)$ and $\omega(G)$ denote the vertex independence number and the clique number, respectively, of $G$.

Corollary 5. If $G$ is a claw-free graph with $\gamma(G) \leq \gamma(\bar{G})-2$, then $\gamma(G) \leq 2$ or $\gamma(G) \leq \omega(G) / 2=\alpha(\bar{G}) / 2$.

### 2.3. Graphs $G$ with a $\gamma(G)$-bad vertex

Recall that a vertex in a graph $G$ is a $\gamma(G)$-bad vertex if it is contained in no $\gamma(G)$ set. We establish next an upper bound on the sum of the domination numbers of a graph $G$ and its complement $\bar{G}$ in terms of the degree of a $\gamma(G)$-bad vertex.

Theorem 6. If a graph $G$ contains a vertex $v$ that is a $\gamma(\bar{G})$-bad vertex, then $\gamma(G)+\gamma(\bar{G}) \leq d_{G}(v)+3$.

Proof. Let $G=(V, E)$ be a graph that contains a $\gamma(\bar{G})$-bad vertex $v$. Let $A=$ $N_{G}(v)$, and so $|A|=d_{G}(v)$. Since the set $A \cup\{v\}$ is a dominating set in $\bar{G}$, we have that $\gamma(\bar{G}) \leq|A|+1$. However if $\gamma(\bar{G})=|A|+1$, then $A \cup\{v\}$ is a $\gamma(\bar{G})$-set, contradicting the fact that $v$ is a $\gamma(\bar{G})$-bad vertex. Therefore, $\gamma(\bar{G})<|A|+1$, or, equivalently, $|A| \geq \gamma(\bar{G})$.

Let $B=V \backslash N_{G}[v]$. If $B=\emptyset$, then $v$ dominates $V$ in the graph $G$, implying that $v$ is isolated in $\bar{G}$ and therefore belongs to every $\gamma(\bar{G})$-set, a contradiction. Hence, $B \neq \emptyset$. We show next that each vertex in $B$ has at least $\bar{\gamma}-1$ neighbors in $G$ that belong to the set $A$. Let $x \in B$, and let $A_{x}=A \cap N_{G}(x)$. Then in the graph $\bar{G}$, the vertex $x$ dominates the set $A \backslash A_{x}$. Thus since the vertex $v$ dominates the set $B$ in $\bar{G}$, we have that the set $A_{x} \cup\{v, x\}$ is a dominating set in $\bar{G}$, implying that $\gamma(\bar{G}) \leq\left|A_{x}\right|+2$. However if $\gamma(\bar{G})=\left|A_{x}\right|+2$, then $A_{x} \cup\{v, x\}$ is a $\gamma(\bar{G})$-set, contradicting the fact that $v$ is a $\gamma(\bar{G})$-bad vertex. Therefore, $\gamma(\bar{G})<\left|A_{x}\right|+2$, or, equivalently, $\gamma(\bar{G}) \leq\left|A_{x}\right|+1$. Thus in the graph $\bar{G}$, we have that $d_{A}(x)=\left|A_{x}\right| \geq \gamma(\bar{G})-1$. This is true for every vertex $x \in B$.

Recall that $|A| \geq \gamma(\bar{G})$. Let $A^{\prime}$ be an arbitrary subset of $A$ of cardinality $\gamma(\bar{G})-2$, and let $A^{*}=A \backslash A^{\prime}$. Thus, $\left|A^{\prime}\right|=\gamma(\bar{G})-2$ and $\left|A^{*}\right|=|A|-\left|A^{\prime}\right|=$ $d_{G}(v)-\gamma(\bar{G})+2$. Since $d_{A}(x) \geq \gamma(\bar{G})-1$ for every vertex $x \in B$, the set $A^{*}$ dominates the set $B$ in $G$. Thus, $A^{*} \cup\{v\}$ is a dominating set in $G$, implying that $\gamma(G) \leq\left|A^{*}\right|+1=d_{G}(v)-\gamma(\bar{G})+3$.

As a consequence of Theorem 6, we have the following result.
Corollary 6. If $G$ is an r-regular graph that contains a $\gamma(\bar{G})$-bad vertex, then $\gamma(G)+\gamma(\bar{G}) \leq r+3$.

### 2.4. Domination and planarity

In this section, we study some relationships between planarity, the crossing number of $G$ and the domination number of $\bar{G}$. Fundamental to our results in this section is the famous Four Color Theorem.

Theorem 7 [1]. If $G$ is a planar graph, then $\chi(G) \leq 4$.
We first establish the following upper bound on the domination number of the complement of a graph. For this purpose, for a vertex $v$ in a graph $G$, we denote by $G_{v}$ the subgraph of $G$ induced by the neighbors of $v$; that is, $G_{v}=G[N(v)]$. If $\mathcal{C}$ is a minimum coloring of the vertices of $G_{v}$, and $S$ is a set of vertices comprising of exactly one vertex from each color class of $\mathcal{C}$, then the set $S \cup\{v\}$ forms a dominating set of $\bar{G}$, implying that $\gamma(\bar{G}) \leq|\mathcal{C}|+1=\chi\left(G_{v}\right)+1$. We state this formally as follows.

Observation 8. If $v$ is an arbitrary vertex in a graph $G$, then $\gamma(\bar{G}) \leq \chi\left(G_{v}\right)+1$.
As a consequence of Theorem 7 and Observation 8, we have the following results.

Corollary 7. If a graph $G$ contains a vertex $v$ with the property that $G_{v}$ is a planar graph, then $\gamma(\bar{G}) \leq 5$.

Corollary 8. If a graph $G$ satisfies $\gamma(G)>2 c r(G)$, then $\gamma(\bar{G}) \leq 5$.
Proof. Let $G^{*}$ be a drawing of $G$ in the plane with exactly $\operatorname{cr}(G)$ crossing edges, and let $S$ be the set of vertices of $G$ incident with at least one crossing edge of $G^{*}$. Clearly, $|S| \leq 2 c r(G)$. Since, by assumption, $\gamma(G)>2 c r(G)$, it follows there exists some vertex $v$ in $G$ that is not dominated by $S$. This implies that $G_{v}$ is a planar graph. Thus, by Corollary $7, \gamma(\bar{G}) \leq 5$.

## 3. Total, Connected, Restrained, and Clique Domination

In this section, we establish relationships involving the domination, total domination, restrained domination, connected domination and clique domination numbers of a graph. We begin with the following lemma.

Lemma 9. If there exists a $\gamma(G)$-set for a graph $G$ that is not a dominating set in $\bar{G}$, then $\gamma_{t}(G) \leq \gamma_{c}(G) \leq \gamma(G)+1$.

Proof. Let $S$ be a $\gamma(G)$-set in a graph $G=(V, E)$ that is not a dominating set in $\bar{G}$. Then there exists a vertex $v \in V \backslash S$ that is not adjacent to any vertex of $S$ in $\bar{G}$. Hence in $G$, the vertex $v$ is adjacent to every vertex of $S$, implying that the graph $G[S \cup\{v\}]$ is connected. Since every superset of a dominating set is also a dominating set, the set $S \cup\{v\}$ is a CD-set, and so $\gamma_{c}(G) \leq|S \cup\{v\}|=\gamma(G)+1$. Since the total domination of a graph is at most its connected domination number, the desired result follows from the observation that $\gamma_{t}(G) \leq \gamma_{c}(G)$.

By the contrapositive of Lemma 9, we note that if a graph $G$ satisfies $\gamma_{t}(G) \geq$ $\gamma(G)+2$, then every $\gamma(G)$-set is a dominating set in $\bar{G}$. Further as a consequence of Lemma 9 and the well-known result due to Jaeger and Payan [11] that if $G$ is a graph of order $n$, then $\gamma(G) \gamma(\bar{G}) \leq n$, we have the following result.

Corollary 10. Let $G$ be a graph of order $n$ satisfying $\gamma(G)<\gamma(\bar{G})$. Then the following holds.
(a) $\gamma_{t}(G) \leq \gamma_{c}(G) \leq \gamma(G)+1$.
(b) $\gamma_{c}(G) \leq(1+\sqrt{4 n+1}) / 2$.

Proof. Part (a) is an immediate consequence of Lemma 9. To prove part (b), let $G$ be a graph of order $n$ satisfying $\gamma(G)<\gamma(\bar{G})$. By part (a) and our assumption that $\gamma(G) \leq \gamma(\bar{G})-1$, we have that $\gamma_{c}(G) \leq \gamma(G)+1 \leq \gamma(\bar{G})$. Applying the result due to Jaeger and Payan, we therefore have that $\left(\gamma_{c}(\bar{G})-1\right) \gamma_{c}(G) \leq \gamma(G) \gamma(\bar{G}) \leq$ $n$. Solving for $\gamma_{c}(G)$, we have that $\gamma_{c}(G) \leq(1+\sqrt{4 n+1}) / 2$.

In the following result, we consider the case when $\gamma(G) \leq \gamma(\bar{G})+1$.

Theorem 9. Let $G$ be a graph satisfying $\gamma(G) \leq \gamma(\bar{G})+1$. Then the following holds.
(a) If both $G$ and $\bar{G}$ are connected, then $\gamma_{c}(G) \leq \gamma(G)+1$ or $\gamma_{c}(\bar{G}) \leq \gamma(\bar{G})+1$.
(b) If both $G$ and $\bar{G}$ are isolate-free, then $\gamma_{t}(G) \leq \gamma(G)+1$ or $\gamma_{t}(\bar{G}) \leq \gamma(\bar{G})+1$.

Proof. Let $G=(V, E)$, and let $S$ be a $\gamma(G)$-set in the graph. We first establish part (a). Suppose that both $G$ and $\bar{G}$ are connected. If $G[S]$ is connected, then $S$ is a CD-set in $G$, implying that $\gamma_{c}(G) \leq|S|=\gamma(G)$. Hence we may assume that $G[S]$ is not connected, for otherwise part (a) is immediate. This implies that $\bar{G}[S]$ is connected. If the set $S$ is not a dominating set in $\bar{G}$, then by Lemma 9 , we have that $\gamma_{c}(G) \leq \gamma(G)+1$. If the set $S$ is a dominating set in $\bar{G}$, then $S$ is a CD-set in $\bar{G}$, implying that $\gamma_{c}(\bar{G}) \leq|S|=\gamma(G) \leq \gamma(\bar{G})+1$. This proves part (a).

Next we prove part (b). Suppose that both $G$ and $\bar{G}$ are isolate-free. If $G[S]$ is isolate-free, then $S$ is a TD-set in $G$, implying that $\gamma_{t}(G) \leq|S|=\gamma(G)$. Hence we may assume that $G[S]$ contains an isolated vertex, for otherwise part (b) is immediate. This implies that $\bar{G}[S]$ is connected. If the set $S$ is not a dominating set in $\bar{G}$, then by Lemma 9 we have that $\gamma_{t}(G) \leq \gamma(G)+1$. If the set $S$ is a dominating set in $\bar{G}$, then $S$ is a TD-set in $\bar{G}$, implying that $\gamma_{t}(\bar{G}) \leq|S|=$ $\gamma(G) \leq \gamma(\bar{G})+1$. This proves part (b).

We establish next an upper bound on the total domination number of a graph in terms of its domination number and the domination number of its complement.

Theorem 10. Let $G$ be an isolate-free graph, and let $S$ be a $\gamma(G)$-set. If $s$ is the number of isolated vertices in $G[S]$, then $\gamma_{t}(G) \leq \gamma(G)+\lceil s /(\gamma(\bar{G})-1)\rceil$.

Proof. Let $G=(V, E)$. Since $G$ is isolate-free, we note that $\gamma(\bar{G}) \geq 2$. Let $I$ be the set of isolated vertices in $G[S]$, and so $s=|I|$. Let $k=\lceil s /(\bar{\gamma}-1)\rceil$, and partition the set $I$ into $k$ sets $I_{1}, \ldots, I_{k}$ each of cardinality at most $\bar{\gamma}-1$. Thus, $I=\bigcup_{i=1}^{k} I_{i}$ and $1 \leq\left|I_{i}\right| \leq \bar{\gamma}-1$ for each $i, 1 \leq i \leq k$. In particular, we note that no set $I_{i}$ dominates $V$ in $\bar{G}$. For each set $I_{i}, 1 \leq i \leq k$, select one vertex $w_{i} \in V \backslash I_{i}$ that is not dominated by $I_{i}$ in $\bar{G}$, and let $W=\bigcup_{i=1}^{k}\left\{w_{i}\right\}$. Then, $|W| \leq k$. We note that in the graph $G$, the vertex $w_{i}$ is adjacent to every vertex of $I_{i}$, and so $S \cup W$ is a TD-set in $G$. Hence, $\gamma_{t}(G) \leq|S \cup W| \leq|S|+|W| \leq$ $\gamma(G)+k=\gamma(G)+\lceil s /(\bar{\gamma}-1)\rceil$.

As an immediate consequence of Theorem 10, we have the following upper bound on the total domination number of a graph.
Corollary 11. If $G$ is an isolate-free graph, then $\gamma_{t}(G) \leq \gamma(G)+\left\lceil\frac{\gamma(G)}{\gamma(\bar{G})-1}\right\rceil$.
Theorem 11. If $G$ is a graph with $\gamma_{t}(G) \geq \gamma(G)+2$, then $\gamma_{t}(\bar{G}) \leq 1+\left\lceil\frac{\delta(G)}{\gamma(G)}\right\rceil$.

Proof. Let $G=(V, E)$ be a graph with $\gamma_{t}(G) \geq \gamma(G)+2$, and let $v$ be a vertex of $G$ having degree $\delta(G)$. Let $A=N_{G}(v)$, and so $|A|=\delta(G)$. Let $k=\lceil\delta(G) / \gamma(G)\rceil$ and partition the set $A$ into $k$ sets $A_{1}, \ldots, A_{k}$ each of cardinality at most $\gamma(G)$. Thus, $A=\bigcup_{i=1}^{k} A_{i}$ and $1 \leq\left|A_{i}\right| \leq \gamma(G)$ for each $i, 1 \leq i \leq k$. If the set $A_{i}$ dominates $V \backslash N_{G}[v]$ in $G$ for some $i, 1 \leq i \leq k$, then the set $A_{i} \cup\{v\}$ is a TD-set in $G$, implying that $\gamma_{t}(G) \leq\left|A_{i}\right|+1 \leq \gamma(G)+1$, a contradiction. Therefore, no set $A_{i}$ dominates $V \backslash N_{G}[v]$ in $G$. For each set $A_{i}, 1 \leq i \leq k$, select one vertex $a_{i} \in V \backslash N_{G}[v]$ that is not dominated by $A_{i}$ in $G$, and let $A^{\prime}=\bigcup_{i=1}^{k}\left\{a_{i}\right\}$. Then, $\left|A^{\prime}\right| \leq k$ and $A^{\prime}$ dominates $A$ in $\bar{G}$. Therefore, the set $A^{\prime} \cup\{v\}$ is a TD-set in $\bar{G}$, and so $\gamma_{t}(\bar{G}) \leq\left|A^{\prime}\right|+1 \leq k+1=1+\lceil\delta(G) / \gamma(G)\rceil$.

Next we consider the restrained domination number. We first prove a general lemma.

Lemma 12. If a graph $G$ has a $\gamma(G)$-set $S$ such that the induced subgraph $G[V \backslash S]$ has an isolated vertex, then $\gamma(\bar{G}) \leq 3$.
Proof. Let $S$ be a $\gamma(G)$-set such that $G[V \backslash S]$ has an isolated vertex, say $w$. If $G[S]$ has an isolated vertex $v$, then $\{v, w\}$ is dominating set of $\bar{G}$, and so $\gamma(\bar{G}) \leq 2$. If $G[S]$ contains no isolated vertices, then by the minimality of $S$, for each $v \in S$, there exists a vertex, say $v^{\prime} \in V \backslash S$, such that $N\left(v^{\prime}\right) \cap S=\{v\}$. In this case, the set $\left\{v, w, v^{\prime}\right\}$ is a dominating set of $\bar{G}$, implying that $\gamma(\bar{G}) \leq 3$.

As an immediate consequence of Lemma 12, we have the following result.
Corollary 13. If a graph $G$ has $\gamma(\bar{G}) \geq 4$, then every $\gamma(G)$-set is a $\gamma_{r}(G)$-set. In particular, $\gamma(G)=\gamma_{r}(G)$.

We close this section with two results about the clique domination number of a graph.
Theorem 12. If $G$ is a graph with $\gamma_{t}(G) \geq \gamma(G)+2$, then $\gamma_{\mathrm{cl}}(\bar{G}) \leq \gamma(G)$. Moreover, if $G$ is claw-free, then $\gamma_{\mathrm{cl}}(\bar{G}) \leq 3$.

Proof. Let $G$ be a graph with $\gamma_{t}(G) \geq \gamma(G)+2$, and let $S$ be a $\gamma(G)$-set. Further, let $I(S)$ be the set of isolated vertices in $G[S]$. If $I(S)=\emptyset$, then $S$ is a TD-set of $G$, implying that $\gamma_{t}(G) \leq|S|=\gamma(G)$, a contradiction. Hence, $I(S) \neq \emptyset$. We show that $I(S)$ dominates $\bar{G}$. Suppose to the contrary that there exists a vertex $v$ that is not adjacent to any vertex of $I(S)$ in $\bar{G}$. Then in the graph $G$, the vertex $v$ is adjacent to every vertex of $I(S)$, implying that $S \cup\{v\}$ is a TD-set for $G$, and so $\gamma_{t}(G) \leq|S|+1=\gamma(G)+1$, a contradiction. Hence, the set $I(S)$ dominates $\bar{G}$. Since $I(S)$ is an independent set in $G$, it forms a clique in $\bar{G}$. Therefore, $I(S)$ is a dominating clique in $\bar{G}$, implying that $\gamma_{\mathrm{cl}}(\bar{G}) \leq|I(S)| \leq \gamma(G)$.

Now, suppose that $G$ is claw free. If $|I(S)| \leq 3$, then the result follows. Hence, we may assume that $|I(S)| \geq 4$ and there exists a subset $\{a, b, c\} \subseteq I(S)$
that is not a dominating set in $\bar{G}$. Then there exists a vertex $v$ that is not adjacent to $a, b$, or $c$ in $\bar{G}$. But then in the graph $G$, we have that $\{a, b, c, v\}$ induces a claw, a contradiction. Therefore, every subset of $I(S)$ of cardinality 3 is a dominating set in $\bar{G}$, implying that $\gamma_{\mathrm{cl}}(\bar{G}) \leq 3$.

## 4. Bounds on the Domination Number of a Graph in Terms of the Adjacency Matrix of its Complement

We begin this section by stating two well-known theorems. The first result counts the number of walks of length $k$ for an arbitrary positive integer $k$ in a graph (see [3]; see also Theorem 1.17 in [5]). The second result is a consequence of a result due to Vizing [16] and provides an upper bound for the domination number of a graph in terms of its order and size.

Theorem 13 [3]. Let $G$ be a graph of order $n$ with $V(G)=\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$ and with adjacency matrix $A$. For each positive integer $k$, the number of different walks of length $k$ from the vertex $v_{i}$ to the vertex $v_{j}$ is the $(i, j)$-entry in the matrix $A^{k}$.

Theorem 14 [16]. If $G$ is graph of order $n$ and size $m$, then $\gamma(G) \leq n+1-$ $\sqrt{1+2 m}$.

Let $G$ be a graph of order $n$ with $V(G)=\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$ and with adjacency matrix $A$, and let $a_{i j}^{(k)}$ denote the $(i, j)$-entry in $A^{k}$. Recall that if $v$ is a vertex in $G$, then the subgraph of $G$ induced by $N_{G}(v)$ is called the link of $v$ and is denoted by $\mathcal{L}(v)$, while the subgraph of $\bar{G}$ induced by $N_{G}(v)$ is denoted $\overline{\mathcal{L}}(v)$. Theorem 13 implies that the $(i, i)$-entry of $A^{2}, 1 \leq i \leq n$, is the degree $d_{G}\left(v_{i}\right)$ of $v_{i}$, and the $(i, i)$-entry of $A^{3}, 1 \leq i \leq n$, is equal to twice the number of edges in $\mathcal{L}\left(v_{i}\right)$. Suppose that $a_{i i}^{(3)}<a_{i i}^{(2)}$ for some $i, 1 \leq i \leq n$. Since $a_{i i}^{(2)}=d_{G}\left(v_{i}\right)$ and $\frac{1}{2} a_{i i}^{(3)}$ is the number of edges in $\mathcal{L}\left(v_{i}\right)$, this implies that $\mathcal{L}\left(v_{i}\right)$ contains an isolated vertex, $v$ say. Thus the set $\left\{v, v_{i}\right\}$ is a dominating set in the graph $\bar{G}$, implying that $\gamma(\bar{G}) \leq 2$. We state this formally as follows.
Observation 15. Let $G$ be an isolate-free graph of order $n$ with adjacency matrix A. If the $(i, i)$-entry of $A^{3}$ is less than the $(i, i)$-entry of $A^{2}$ for some $i, 1 \leq i \leq n$, then $\gamma(\bar{G}) \leq 2$.

Using Observation 15, we obtain the following bound on the domination number of the complement of a graph.
Theorem 16. Let $G$ be a graph of order $n$ with adjacency matrix $A$, and let $a_{i j}^{(k)}$ denote the $(i, j)$-entry in $A^{k}$. For every $i, 1 \leq i \leq n$, we have that

$$
\gamma(\bar{G}) \leq a_{i i}^{(2)}+2-\sqrt{1+a_{i i}^{(2)}\left(a_{i i}^{(2)}-1\right)-a_{i i}^{(3)}} .
$$

Proof. Let $i$ be an arbitrary integer with $1 \leq i \leq n$. Since $a_{i i}^{(2)}=d_{G}\left(v_{i}\right)$ and $\frac{1}{2} a_{i i}^{(3)}$ is the number of edges in $\mathcal{L}\left(v_{i}\right)$, this implies that $\overline{\mathcal{L}}\left(v_{i}\right)$ has order $a_{i i}^{(2)}$ and size

$$
\binom{a_{i i}^{(2)}}{2}-\frac{1}{2} a_{i i}^{(3)}=\frac{1}{2}\left(a_{i i}^{(2)}\left(a_{i i}^{(2)}-1\right)-a_{i i}^{(3)}\right) .
$$

Thus, by Theorem 14, we have that

$$
\gamma\left(\overline{\mathcal{L}}\left(v_{i}\right)\right) \leq a_{i i}^{(2)}+1-\sqrt{1+a_{i i}^{(2)}\left(a_{i i}^{(2)}-1\right)-a_{i i}^{(3)}} .
$$

The desired bound now follows from the observation that every $\gamma\left(\overline{\mathcal{L}}\left(v_{i}\right)\right)$-set can be extended to a dominating set in $\bar{G}$ by adding to it the vertex $v_{i}$, and so $\gamma(\bar{G}) \leq \gamma\left(\overline{\mathcal{L}}\left(v_{i}\right)\right)+1$.
