#### Abstract

Let $G=(V, E)$ be a finite graph and $r \geq 1$ be an integer. For $v \in V$, let $B_{r}(v)=\{x \in V: d(v, x) \leq r\}$ be the ball of radius $r$ centered at $v$. A set $C \subseteq V$ is an $r$-dominating code if for all $v \in V$, we have $B_{r}(v) \cap C \neq \emptyset$; it is an $r$-locating-dominating code if for all $v \in V$, we have $B_{r}(v) \cap C \neq \emptyset$, and for any two distinct non-codewords $x \in V \backslash C, y \in V \backslash C$, we have $B_{r}(x) \cap C \neq B_{r}(y) \cap C$; it is an $r$-identifying code if for all $v \in V$, we have $B_{r}(v) \cap C \neq \emptyset$, and for any two distinct vertices $x \in V, y \in V$, we have $B_{r}(x) \cap C \neq B_{r}(y) \cap C$. We denote by $\gamma_{r}(G)$ (respectively, $l d_{r}(G)$ and $\left.i d_{r}(G)\right)$ the smallest possible cardinality of an $r$-dominating code (respectively, an $r$-locating-dominating code and an $r$-identifying code). We study how small and how large the three differences $i d_{r}(G)-l d_{r}(G), i d_{r}(G)-\gamma_{r}(G)$ and $l d_{r}(G)-\gamma_{r}(G)$ can be.

Keywords: graph theory, dominating set, locating-dominating code, identifying code, twin-free graph.
2010 Mathematics Subject Classification: 68R10, 05C90, 94C12, 94B60, 94B65.

## 1. Introduction

### 1.1. Definitions and notation

For graph theory, we refer to, e.g., [1, 2] or [8]; for the vast topic of domination in graphs, see [13]. For locating-dominating codes, see the first papers [7] and [18], for identifying codes, see the seminal paper [14]; for both, see also the large bibliography at [15].

We shall denote by $G=(V, E)$ a finite, simple, undirected graph with vertex set $V$ and edge set $E$, where an edge between $x \in V$ and $y \in V$ is indifferently denoted by $x y$ or $y x$. The order of the graph is its number of vertices, $|V|$. Our graphs will generally be connected. The distance between two vertices $x \in V$, $y \in V$, will be denoted by $d_{G}(x, y)$, or $d(x, y)$ when there is no ambiguity.

For an integer $k \geq 2$, the $k$-th transitive closure, or $k$-th power, of $G=(V, E)$ is the graph $G^{k}=\left(V, E^{k}\right)$ defined by $E^{k}=\left\{u v: u \in V, v \in V, 0<d_{G}(u, v) \leq k\right\}$. For a given graph $G^{*}$, any graph $G$ such that $G^{k}=G^{*}$ is called a $k$-th root of $G^{*}$; such roots do not always exist.

For any integer $r \geq 1$, and for every vertex $x \in V$, we denote by $B_{G, r}(x)$ (and $B_{r}(x)$ when there is no ambiguity) the ball of radius $r$ centered at $x$, i.e., the set of vertices at distance at most $r$ from $x$ :

$$
B_{r}(x)=\{y \in V: d(x, y) \leq r\}
$$

Whenever $x \in B_{r}(y)$ (which is equivalent to $y \in B_{r}(x)$ ), we say that $x$ and $y$ $r$-dominate or $r$-cover each other. A vertex $x \in V$ is said to be $r$-universal if it $r$-dominates all the vertices, i.e., if $B_{r}(x)=V$. When three vertices $x, y, z$ are such that $z \in B_{r}(x)$ and $z \notin B_{r}(y)$, we say that $z r$-sepatares $x$ and $y$ in $G$ (note that $z=x$ is possible). A set of vertices is said to $r$-separate $x$ and $y$ if at least one of its element does.

Let $C \subseteq V$ be a set of vertices; the set $C$ is called a code, and its elements codewords.

A code $C$ is said to be an $r$-dominating set or an $r$-dominating code ( $r$ - D code for short) if for all $x \in V$, we have $B_{r}(x) \cap C \neq \emptyset$. One can also find the terminology dominating set at distance $r$, or distance $r$ dominating set.

A code $C$ is said to be $r$-locating-dominating ( $r$-LD for short) if for all $x \in V$, we have $B_{r}(x) \cap C \neq \emptyset$, and for any two distinct non-codewords $x \in V \backslash C$, $y \in V \backslash C$, we have $B_{r}(x) \cap C \neq B_{r}(y) \cap C$.

A code $C$ is said to be r-identifying ( $r$-ID for short) if for all $x \in V$, we have $B_{r}(x) \cap C \neq \emptyset$, and for any two distinct vertices $x \in V, y \in V$, we have $B_{r}(x) \cap C \neq B_{r}(y) \cap C$.

In other words: every vertex must be $r$-dominated by at least one codeword for the three definitions; in addition, every pair of distinct non-codewords (respectively, vertices) must be $r$-separated by an $r$-LD (respectively, $r$-ID) code.

Two vertices $x \in V, y \in V, x \neq y$, are said to be $r$-twins if $B_{r}(x)=B_{r}(y)$. Dominating and locating-dominating codes exist for all graphs. On the other hand, it is easy to see that a graph $G$ admits an $r$-identifying code if and only if

$$
\begin{equation*}
\forall x \in V, \forall y \in V, x \neq y: B_{r}(x) \neq B_{r}(y) \tag{1}
\end{equation*}
$$

A graph satisfying (1) is called $r$-identifiable or $r$-twin-free.

### 1.2. Aim of the paper

For all three concepts, we are often interested in finding the minimum sized codes. We denote by $\gamma_{r}(G)$ (respectively, $l d_{r}(G)$ and $\left.i d_{r}(G)\right)$ the smallest possible cardinality of an $r$-dominating code (respectively, an $r$-locating-dominating code and an $r$-identifying code when $G$ is $r$-twin-free). We call $\gamma_{r}(G)$ the $r$-domination number of $G$. Since obviously an $r$-ID code (when it exists) is an $r$-LD code which in turn is an $r$-D code, the following inequalities hold:

$$
\gamma_{r}(G) \leq l d_{r}(G) \leq i d_{r}(G)
$$

In other words, location-domination is more "expensive" than domination, and identification is more expensive than location-domination. In this paper, we compare the respective "costs" for these three definitions.

More precisely, denoting

$$
\mathcal{G}_{r, n}=\{G: G \text { is } r \text {-twin-free, connected, with order } n \geq 2\},
$$

and $\mathcal{G}_{r, n}^{t w}=\{G: G$ has $r$-twins and is connected, with order $n \geq 2\}$,
we study the following maximum and minimum differences:

- $F_{i d, l d}(r, n)=\max \left\{i d_{r}(G)-l d_{r}(G): G \in \mathcal{G}_{r, n}\right\}$,
- $f_{i d, l d}(r, n)=\min \left\{i d_{r}(G)-l d_{r}(G): G \in \mathcal{G}_{r, n}\right\}$,
- $F_{i d, \gamma}(r, n)=\max \left\{i d_{r}(G)-\gamma_{r}(G): G \in \mathcal{G}_{r, n}\right\}$,
- $f_{i d, \gamma}(r, n)=\min \left\{i d_{r}(G)-\gamma_{r}(G): G \in \mathcal{G}_{r, n}\right\}$.

For D- and LD-codes, we have two cases, (a) and (b), which study graphs which are without or with twins, respectively:
(a) • $F_{l d, \gamma}(r, n)=\max \left\{l d_{r}(G)-\gamma_{r}(G): G \in \mathcal{G}_{r, n}\right\}$,

- $f_{l d, \gamma}(r, n)=\min \left\{l d_{r}(G)-\gamma_{r}(G): G \in \mathcal{G}_{r, n}\right\} ;$
these two functions are considered on the same set of graphs (the twin-free graphs) as the four functions involving identification, unlike the two functions below:
(b) $\bullet F_{l d, \gamma}^{t w}(r, n)=\max \left\{l d_{r}(G)-\gamma_{r}(G): G \in \mathcal{G}_{r, n}^{t w}\right\}$,
- $f_{l d, \gamma}^{t w}(r, n)=\min \left\{l d_{r}(G)-\gamma_{r}(G): G \in \mathcal{G}_{r, n}^{t w}\right\}$.

Finally, if we want to consider all the connected graphs of order $n$, twin-free or not, the result is obviously obtained by taking $\max \left\{F_{l d, \gamma}(r, n), F_{l d, \gamma}^{t w}(r, n)\right\}$ and $\min \left\{f_{l d, \gamma}(r, n), f_{l d, \gamma}^{t w}(r, n)\right\}$.

## 2. Some Earlier Results

The following easy four lemmas are as old as the definitions of dominating, locating-dominating or identifying codes. We give the proofs only for the first two.

Lemma 1. (a) For any graph $G=(V, E)$ of order $n$ and any integer $r \geq 1$, we have

$$
\begin{equation*}
l d_{r}(G) \geq\left\lceil\log _{2}\left(n-l d_{r}(G)+1\right)\right\rceil \tag{2}
\end{equation*}
$$

(b) For any integer $r \geq 1$ and any $r$-twin-free graph $G=(V, E)$ of order $n$, we have

$$
\begin{equation*}
i d_{r}(G) \geq\left\lceil\log _{2}(n+1)\right\rceil \tag{3}
\end{equation*}
$$

Proof. (a) Let $C$ be any $r$-LD code in $G$. All the $n-|C|$ non-codewords $v \in V \backslash C$ must be given nonempty and distinct sets $B_{r}(v) \cap C$ constructed with the $|C|$ codewords, so $2^{|C|}-1 \geq n-|C|$, from which (2) follows when $C$ is optimal;
(b) the argument is the same, but we have to consider all the $n$ vertices $v \in V$, so $2^{|C|}-1 \geq n$.

Lemma 2. Let $r \geq 2$ be any integer and $G=(V, E)$ be a graph.
(a) A code $C$ is 1-locating-dominating in $G^{r}$, the $r$-th power of $G$, if and only if it is $r$-locating-dominating in $G$.
(b) A code $C$ is 1-identifying in $G^{r}$ if and only if it is $r$-identifying in $G$.
(c) A code $C$ is 1-dominating in $G^{r}$ if and only if it is $r$-dominating in $G$.

Proof. (a) For every vertex $v \in V$, we have

$$
\left\{c \in C: d_{G}(v, c) \leq r\right\}=\left\{c \in C: d_{G^{r}}(v, c) \leq 1\right\},
$$

so if for all $v \in V \backslash C$, the sets on the left-hand side of the equality are nonempty and distinct, then the sets on the right side also are, and vice-versa; (b) the same proof, for all $v \in V$; (c) the same proof, for all $v \in V$, with only nonemptiness to be checked.

Lemma 3. (a) For any integer $r \geq 1$, if $G$ is a connected graph of order $n$, then

$$
\begin{equation*}
l d_{r}(G) \leq n-1 \tag{4}
\end{equation*}
$$

(b) If $G$ is an $r$-twin-free graph of order $n$, then $n \geq 2 r+1$, and the only $r$-twin-free graph of order $2 r+1$ is the path.
(c) If $G$ is an $r$-twin-free cycle of order $n$, then $n \geq 2 r+2$.

The following obvious lemma is often used implicitly.
Lemma 4. Let $r \geq 1$ be any integer and $G=(V, E)$ be a graph.
(a) If $C$ is $r$-dominating in $G$, so is any set $S \supset C$.
(b) If $C$ is r-locating-dominating in $G$, so is any set $S \supset C$.
(c) If $C$ is r-identifying in $G$, so is any set $S \supset C$.

Proposition 5. (a) [16], [13, p. 41] If $G$ has no isolated vertices (in particular, if $G$ is connected) and has order $n$, then $\gamma_{1}(G) \leq \frac{n}{2}$.
(b) [11] If $G$ is a 1-twin-free graph, then $i d_{1}(G) \leq 2 l d_{1}(G)$.

The following result is from [3], but a shorter proof can be found in [12].
Proposition 6. If $G$ is a connected 1-twin-free graph of order $n$, then $i d_{1}(G) \leq$ $n-1$.

Corollary 7. Let $r \geq 1$ be any integer.
(i) If $G$ is a connected graph of order $n$, then $\gamma_{r}(G) \leq \frac{n}{2}$.
(ii) If $G$ is an $r$-twin-free graph, then $d_{r}(G) \leq 2 l d_{r}(G)$.
(iii) If $G$ is a connected $r$-twin-graph of order $n$, then

$$
\begin{equation*}
i d_{r}(G) \leq n-1 \tag{5}
\end{equation*}
$$

Proof. Use the $r$-th power of $G$, together with the previous two propositions.
Both lower bounds (2), (3) and upper bounds (4), (5) for $r$-LD and $r$-ID codes can be reached [6], as well as all intermediate values [4], [5].

The graphs $G$ of order $n$ such that $i d_{1}(G)=n-1$ have been characterized in [10], but the case $r \geq 2$ remains open.

## 3. Some Important Graphs

The following three lemmas describe three useful graphs, which have been used in previous papers. The first graph is the "star".

Lemma 8. For $n \geq 3$, let $G_{n}$ be the tree consisting of $n$ vertices $v_{0}, v_{1}, \ldots, v_{n-1}$, and $n-1$ edges $v_{0} v_{i}, 1 \leq i \leq n-1$. Then

$$
\gamma_{1}\left(G_{n}\right)=1, l d_{1}\left(G_{n}\right)=n-1 \text { and } i d_{1}\left(G_{n}\right)=n-1
$$

Proof. (a) Since $v_{0}$ is a 1 -universal vertex, we have $\gamma_{1}\left(G_{n}\right)=1$.
(b) It is quite straightforward to check that taking for codewords any set of $n-1$ vertices is necessary and sufficient to obtain a 1-LD or 1-ID code, except for $n=3$, when only $\left\{v_{1}, v_{2}\right\}$ is a 1 -ID code.

The second graph, denoted $G_{2 p}^{*}$, has even order and is the complete graph (or clique) minus a perfect matching; see Figure 1.

| $v_{0}$ | 0 | 0$v_{1}$  <br> $v_{p}$ 0$\quad<$$v_{p-1}$ <br> $v_{p+1}$ | $\cdots$ | 0 |
| :---: | :---: | :---: | :---: | :---: |
| $v_{2 p-1}$ |  |  |  |  |$|$

Figure 1. The complement of $G_{2 p}^{*}$ : only the missing edges $v_{0} v_{p}, \ldots, v_{p-1} v_{2 p-1}$ are represented.

Lemma 9. Let $p \geq 2$ and $G_{2 p}^{*}=\left(V_{2 p}^{*}, E_{2 p}^{*}\right)$, with $V_{2 p}^{*}=\left\{v_{0}, v_{1}, \ldots, v_{2 p-1}\right\}$, $E_{2 p}^{*}=\left\{v_{i} v_{j}: v_{i} \in V_{2 p}^{*}, v_{j} \in V_{2 p}^{*}, i \neq j, i \neq j+p \bmod 2 p\right\}$. Then

$$
\gamma_{1}\left(G_{2 p}^{*}\right)=2, l d_{1}\left(G_{2 p}^{*}\right)=p \text { and } i d_{1}\left(G_{2 p}^{*}\right)=2 p-1
$$

Proof. For every $v_{i} \in V_{2 p}^{*}$, we have $B_{1}\left(v_{i}\right)=V_{2 p}^{*} \backslash\left\{v_{i+p} \bmod 2 p\right\}$, and for every pair of distinct vertices $v_{i} \in V_{2 p}^{*}, v_{j} \in V_{2 p}^{*}$, we have $B_{1}\left(v_{i}\right) \Delta B_{1}\left(v_{j}\right)=$ $\left\{v_{i+p} \bmod 2 p, v_{j+p} \bmod 2 p\right\}$, where $\Delta$ stands for the symmetric difference.
(a) The fact that $\gamma_{1}\left(G_{2 p}^{*}\right)=2$ is easy to check.
(b) Obviously, $C=\left\{v_{0}, \ldots, v_{p-1}\right\}$ is a 1-LD code, of size $p$. Assume that there is a minimum 1-LD code $C$ with fewer than $p$ elements. Then there is at least one $j$ such that $v_{j} \notin C$ and $v_{j+p \bmod 2 p} \notin C$. Without loss of generality, we may assume that $v_{0} \notin C, v_{p} \notin C$. Then $B_{1}\left(v_{0}\right) \Delta B_{1}\left(v_{p}\right)=\left\{v_{0}, v_{p}\right\}$ leads to $C \cap\left(B_{1}\left(v_{0}\right) \Delta B_{1}\left(v_{p}\right)\right)=\emptyset$, contradicting the definition of a 1-LD code: $v_{0}$ and $v_{p}$ are non-codewords not 1 -separated by any codeword.
(c) We know that at most $2 p-1$ codewords are necessary in any minimum 1ID code $C$; therefore, assume, without loss of generality, that $v_{0} \notin C$. Then for all $j \neq p, B_{1}\left(v_{p}\right) \Delta B_{1}\left(v_{j}\right)=\left\{v_{0}, v_{j+p} \bmod 2 p\right\}$, and, since $v_{p}$ and $v_{j}$ are 1-separated by at least one codeword, we have $\emptyset \neq\left(B_{1}\left(v_{p}\right) \Delta B_{1}\left(v_{j}\right)\right) \cap C \subseteq\left\{v_{j+p} \bmod 2 p\right\}$. So for all values of $j$ but one, the $2 p-1$ distinct vertices $v_{j+p \bmod 2 p}$ are codewords, and $|C| \geq 2 p-1$, i.e., $|C|=2 p-1$.

The third graph is obtained from the previous one by adding one 1 -universal vertex, and its order is odd.

Lemma 10. Let $p \geq 2$ and $G_{2 p+1}^{*}=\left(V_{2 p+1}^{*}, E_{2 p+1}^{*}\right)$, with $V_{2 p+1}^{*}=\left\{v_{0}, v_{1}, \ldots\right.$, $\left.v_{2 p}\right\}, E_{2 p+1}^{*}=\left\{v_{i} v_{j}: v_{i} \in V_{2 p+1}^{*} \backslash\left\{v_{2 p}\right\}, v_{j} \in V_{2 p+1}^{*} \backslash\left\{v_{2 p}\right\}, i \neq j, i \neq j+\right.$ $p \bmod 2 p\} \cup\left\{v_{2 p} v_{j}: v_{j} \in V_{2 p+1}^{*} \backslash\left\{v_{2 p}\right\}\right\}$. Then

$$
\gamma_{1}\left(G_{2 p+1}^{*}\right)=1, l d_{1}\left(G_{2 p+1}^{*}\right)=p \text { and } i d_{1}\left(G_{2 p+1}^{*}\right)=2 p
$$

Proof. (a) The fact that $v_{2 p}$ is 1-universal shows that $\gamma_{1}\left(G_{2 p+1}^{*}\right)=1$.
(b) For 1-LD codes, the argument of the Case (b) of the previous proof can be applied mutatis mutandis, because the 1-universal vertex does not change anything when considering symmetric differences of balls of radius one.
(c) For $i \in\{0, \ldots, 2 p-1\}$, we have $B_{1}\left(v_{2 p}\right) \Delta B_{1}\left(v_{i}\right)=\left\{v_{i+p} \bmod 2 p\right\}$, therefore all vertices but $v_{2 p}$ must be codewords.

Now, what is more difficult and interesting is that the two graphs $G_{2 p}^{*}$ and $G_{2 p+1}^{*}$ just described in Lemmas 9 and 10 admit $r$-th roots for any $r$, if $p$ is sufficiently large [6]. More precisely:

Proposition 11. Let $r \geq 2$ and $p \geq 2$ be integers.
(a) [6, Theorem 5] If $2 p \geq 3 r^{2}$, then there exists a graph $G_{2 p}$ of order $2 p$ such that $\left(G_{2 p}\right)^{r}=G_{2 p}^{*}$.
(b) [6, Theorem 6] If $2 p \geq 3 r^{2}$, then there exists a graph $G_{2 p+1}$ of order $2 p+1$ such that $\left(G_{2 p+1}\right)^{r}=G_{2 p+1}^{*}$.
(c) For $n \geq 3 r^{2}$, there exists a graph $G_{n}$ of even order $n$ such that $\gamma_{r}\left(G_{n}\right)=2$, $l d_{r}\left(G_{n}\right)=\frac{n}{2}$ and $i d_{r}\left(G_{n}\right)=n-1$.
(d) For $n \geq 3 r^{2}+1$, there exists a graph $G_{n}$ of odd order $n$ such that $\gamma_{r}\left(G_{n}\right)=1$, $l d_{r}\left(G_{n}\right)=\frac{n-1}{2}$ and $i d_{r}\left(G_{n}\right)=n-1$.

Proof. (c)-(d). Use the properties of $r$-th powers of graphs (Lemma 2).
See also the constructions presented and discussed immediately after Proposition 23 in Section 7.1.

## 4. The Very Small Cases: $n \leq 4$

Here, we denote by $T_{r}(G)$ the triple $\left(\gamma_{r}(G), l d_{r}(G), i d_{r}(G)\right)$, with the convention that $i d_{r}(G)=$ ? if $G$ is not $r$-twin-free. Figure 2 gives all the nonisomorphic unlabeled connected graphs with two, three or four vertices, together with their triples for $r=1$.

For $r=2$, the triples are, for the nine graphs of Figure 2, respectively: $(1,1, ?) ;(1,2, ?)$ and ( $1,2, ?$ ); ( $1,2, ?$ ), ( $1,3, ?$ ), ( $1,3, ?$ ), ( $1,3, ?$ ), ( $1,3, ?$ ), and $(1,3, ?)$. For $r \geq 3$, the triples are ( $1, n-1$, ?) for all nine graphs. From this, we have the following result.

Proposition 12. We have
(a) $r=1$

$$
n=2: F_{l d, \gamma}^{t w}(1,2)=f_{l d, \gamma}^{t w}(1,2)=0
$$

$$
\begin{aligned}
n=3: & F_{i d, l d}(1,3)=f_{i d, l d}(1,3)=0 ; F_{i d, \gamma}(1,3)=f_{i d, \gamma}(1,3)=1 ; \\
& F_{l d, \gamma}(1,3)=f_{l d, \gamma}(1,3)=1 ; F_{l d, \gamma}^{t w}(1,3)=f_{l d, \gamma}^{t w}(1,3)=1 ; \\
n=4: & F_{i d, l d}(1,4)=1, f_{i d, l d}(1,4)=0 ; F_{i d, \gamma}(1,4)=2, f_{i d, \gamma}(1,4)=1 ; \\
& F_{l d, \gamma}(1,4)=2, f_{l d, \gamma}(1,4)=0 ; F_{l d, \gamma}^{t w}(1,4)=2, f_{l d, \gamma}^{t w}(1,4)=1 ;
\end{aligned}
$$

(b) $r=2$

$$
\begin{aligned}
& n=2: F_{l d, \gamma}^{t w}(2,2)=f_{l d, \gamma}^{t w}(2,2)=0 \\
& n=3: F_{l d, \gamma}^{t w}(2,3)=f_{l d, \gamma}^{t w}(2,3)=1 ; \\
& n=4: F_{l d, \gamma}^{t w}(2,4)=2, f_{l d, \gamma}^{t w}(2,4)=1 ;
\end{aligned}
$$

(c) $r \geq 3$

$$
n \in\{2,3,4\}: F_{l d, \gamma}^{t w}(r, n)=f_{l d, \gamma}^{t w}(r, n)=n-2 .
$$

$$
n=2 \underset{(1,1, ?)}{\circ} \quad n=3 \quad \underset{(1,2,2)}{\circ} \circ
$$

$$
n=4
$$

## 5. Identification vs Domination

First, we construct an infinite family of graphs $G_{n}^{*}$ such that $G_{n}^{*}$ has order $n$ and satisfies $i d_{r}\left(G_{n}^{*}\right)=\gamma_{r}\left(G_{n}^{*}\right)$.

These graphs will have order $n=k(r+1)$ and consist of one cycle of order $k$ and $k$ strings with $r$ vertices each: $G_{n}^{*}=\left(V_{n}^{*}, E_{n}^{*}\right)$, with $V_{n}^{*}=V_{0} \cup\left(\bigcup_{1 \leq i \leq k} V_{i}\right)$ and $E_{n}^{*}=E_{0} \cup\left(\bigcup_{1 \leq i \leq k} E_{i}\right)$, where $V_{0}=\left\{v_{1,0}, v_{2,0}, \ldots, v_{k, 0}\right\}, V_{i}=\left\{v_{i, j}: 1 \leq\right.$ $j \leq r\}$ for $i \in\{1,2, \ldots, k\}, E_{0}=\left\{v_{i, 0} v_{i+1,0}: 1 \leq i \leq k-1\right\} \cup\left\{v_{k, 0} v_{1,0}\right\}$ and $E_{i}=\left\{v_{i, j} v_{i, j+1}: 0 \leq j \leq r-1\right\}$ for $i \in\{1,2, \ldots, k\}$ (see Figure 3(a)).
Proposition 13. For all $r \geq 1$ and $k \geq 2 r+2$, the graph $G_{n}^{*}$ is such that

$$
\gamma_{r}\left(G_{n}^{*}\right)=i d_{r}\left(G_{n}^{*}\right) .
$$

Proof. The $k$ leaves $v_{i, r}$ must be $r$-dominated by at least one codeword, and no vertex can $r$-dominate two leaves, so $\gamma_{r}\left(G_{n}^{*}\right) \geq k$. On the other hand, the code $C=V_{0}$ represented by the black vertices in Figure 3(a) has cardinality $k$, and it is

Figure 3. (a) The graph $G_{n}^{*}$. (b) The graph $G_{n+1}$. The $k$ black vertices represent codewords.
straightforward to check that it is $r$-identifying. Note in particular that vertices in $V_{0}$ are $r$-dominated by exactly $2 r+1$ codewords (this is where the assumption $k \geq 2 r+2$ is crucial, cf. Lemma 3(c)), and vertices $v_{i, j} \in V_{i}$ are $r$-dominated by exactly $2 r-2 j+1$ codewords. See also the proof of Proposition 28 for $r$-LD codes, which is analogous but more intricate.

So $k \leq \gamma_{r}\left(G_{n}^{*}\right) \leq i d_{r}\left(G_{n}^{*}\right) \leq k$.
Second, if we want $n$ to reach all intermediate values between $k(r+1)$ and $(k+$ 1) $(r+1)-1$, we can do so by adding $p \in\{0, \ldots, r\}$ vertices to $G_{n}^{*}$ in the following way: since $p<\frac{k}{2}$, we can add the set of $p$ vertices $W_{p}=\left\{w_{1}, \ldots, w_{p}\right\}$ together with the set of edges $X_{p}=\left\{w_{1} v_{1,0}, w_{1} v_{2,0}, w_{2} v_{3,0}, w_{2} v_{4,0}, \ldots, w_{p} v_{2 p-1,0}, w_{p} v_{2 p, 0}\right\}$, see Figure 3(b) for $p=1$. Setting $G_{n+p}=\left(V_{n}^{*} \cup W_{p}, E_{n}^{*} \cup X_{p}\right)$, we obtain a graph of order $n+p$, for which, due to the assumption $k \geq 2 r+2$ and the remark in the proof of Proposition 13 stating that all vertices in $G_{n}^{*}$ are $r$-dominated by an odd number of codewords, it is again straightforward to check that $C=V_{0}$ is still a (minimum) $r$-ID code. Therefore we have the following.

Proposition 14. For all $r \geq 1, k \geq 2 r+2$ and $p \in\{0, \ldots, r\}$, the graph $G_{k(r+1)+p}$ is such that $\gamma_{r}\left(G_{k(r+1)+p}\right)=i d_{r}\left(G_{k(r+1)+p}\right)$. As a consequence, for all $r \geq 1$ and $n \geq(2 r+2)(r+1)$, we have

$$
f_{i d, \gamma}(r, n)=0 .
$$

In advance of the next sections, we have the following obvious consequence.
Corollary 15. For all $r \geq 1$ and $n \geq(2 r+2)(r+1)$, we have

$$
f_{i d, l d}(r, n)=f_{l d, \gamma}(r, n)=0
$$

For $r=1$, the construction for Propositions 13 and 14 works for $n \geq 8$; however, we have the exact value of $f_{i d, \gamma}(1, n)$ for all $n$, due to an alternative construction.

Proposition 12(a) has already settled the cases $n=3, n=4$. Lemma 1(b) and Proposition 5(a) establish that any (1-twin-free) graph $G$ with five vertices
is such that $i d_{1}(G) \geq 3$ and $\gamma_{1}(G) \leq 2$; on the other hand it is easy to find graphs $G$ of order five with $i d_{1}(G)=3$ and $\gamma_{1}(G)=2$, e.g., the path, so that $f_{i d, \gamma}(1,5)=1$. For even $n, n \geq 6$, and odd $n, n \geq 7$, it is easy to see that Figure 4 gives graphs $G$ such that $i d_{1}(G)=\gamma_{1}(G)=k$.

Figure 4. (a) $n$ even. (b) $n$ odd. The $k$ black vertices represent codewords constituting both a minimum 1-identifying and 1-dominating code.

Proposition 16. (a) For all $n \geq 6$, we have $f_{i d, \gamma}(1, n)=0$; consequently, $f_{i d, l d}(1, n)=f_{l d, \gamma}(1, n)=0$.
(b) For $n \in\{3,4,5\}$, we have $f_{i d, \gamma}(1, n)=1$.

Now how large can the difference $i d_{r}(G)-\gamma_{r}(G)$ be? By Corollary 7(iii), it is at most $n-2$, obtained by graphs $G$ with $i d_{r}(G)=n-1$ and $\gamma_{r}(G)=1$.

We first treat the case $r=1$, which is easy: the star on $n$ vertices (Lemma $8)$ is an example of a graph $G$ with $i d_{1}(G)=n-1$ and $\gamma_{1}(G)=1$.

Proposition 17. For all $n \geq 3$, we have $F_{i d, \gamma}(1, n)=n-2$.
We now turn to the case $r \geq 2$. When $n$ is odd, the answer is given by Proposition 11(d). Again, we can reach $n-2$ for the difference $i d_{r}(G)-\gamma_{r}(G)$. When $n$ is even, the study of all the graphs $G$ of even order $n$ such that $i d_{1}(G)=n-1$ [10] shows that none of them contains a 1-universal vertex, i.e., none of them is such that $\gamma_{1}(G)=1$, except the star; but the star cannot be the power of any graph. Therefore, for $r \geq 2$, there can exist no graph $G$ with even order $n$ such that $i d_{r}(G)=n-1$ and $\gamma_{r}(G)=1$, since the $r$-th power of this graph would contradict the characterization from [10]; consequently the difference $i d_{r}(G)-\gamma_{r}(G)$ is at most $n-3$. On the other hand, Proposition $11(\mathrm{c})$ gives an example achieving $n-3$, and we have proved the following.

Proposition 18. (a) For all $r \geq 2$ and even $n \geq 3 r^{2}$, we have $F_{i d, \gamma}(r, n)=n-3$.
(b) For all $r \geq 2$ and odd $n \geq 3 r^{2}+1$, we have $F_{i d, \gamma}(r, n)=n-2$.

## 6. IDENTIFICATION vS LOCATION-Domination

We have already seen in Corollary 15 that, for $r \geq 1$ and $n \geq(2 r+2)(r+1)$, we have $f_{i d, l d}(r, n)=0$.

For $r=1$, and for all values of $n$, Propositions 12(a) and 16(a) completely settle this case except when $n=5$, where $f_{i d, l d}(1,5)=0$ thanks to the graph $G_{5}$ with vertex set $\left\{v_{1}, v_{2}, v_{3}, v_{4}, v_{5}\right\}$ and edge set $\left\{v_{1} v_{2}, v_{2} v_{3}, v_{3} v_{4}, v_{4} v_{1}, v_{1} v_{5}\right\}$, $i d_{1}\left(G_{5}\right)=l d_{1}\left(G_{5}\right)=3$. Therefore we have the following.

Proposition 19. For all $n \geq 3$, we have $f_{\text {id,ld }}(1, n)=0$.
What about $F_{i d, l d}(r, n)$ ? We can use Corollary $7($ ii $)$ and obtain that any (connected) $r$-twin-free graph $G$ is such that $i d_{r}(G) \leq 2 l d_{r}(G)$. Therefore, $-l d_{r}(G) \leq$ $-\frac{i d_{r}(G)}{2}$, and $i d_{r}(G)-l d_{r}(G) \leq i d_{r}(G)-\frac{i d_{r}(G)}{2} \leq \frac{n-1}{2}$, leading to $i d_{r}(G)-l d_{r}(G) \leq$ $\left\lceil\frac{n}{2}\right\rceil-1$. On the other hand, Proposition 11(c)-(d) gives examples of graphs reaching $\left\lceil\frac{n}{2}\right\rceil-1$.
Proposition 20. For all $r \geq 1$ and $n \geq 3 r^{2}+1$, we have $F_{i d, l d}(r, n)=\left\lceil\frac{n}{2}\right\rceil-1$.
Proposition 21. (a) For all $n \geq 4$, we have $F_{i d, l d}(1, n)=\left\lceil\frac{n}{2}\right\rceil-1$.
(b) $F_{i d, l d}(1,3)=0$.

Proof. Proposition 12(a) settles the case $n=3$.

## 7. Location-Domination vs Domination

### 7.1. Twin-free graphs

We have already seen in Corollary 15 that, for $r \geq 1$ and $n \geq(2 r+2)(r+1)$, we have $f_{l d, \gamma}(r, n)=0$. Moreover, for $r=1$, Propositions 12(a) and 16(a) treat all values of $n$ but $n=5$, for which the path shows that $f_{l d, \gamma}(1,5)=0$.

Proposition 22. (a) For all $n \geq 4$, we have $f_{l d, \gamma}(1, n)=0$.
(b) $f_{l d, \gamma}(1,3)=1$.
(c) For all $r \geq 1$ and $n \geq(2 r+2)(r+1)$, we have $f_{l d, \gamma}(r, n)=0$.

We know, using the example of the star (Lemma 8), that $F_{l d, \gamma}(1, n)=n-2$. What about $F_{l d, \gamma}(r, n)$ for general $r$ ?

On the one hand, Proposition 11(c)-(d) immediately gives examples proving that $F_{l d, \gamma}(r, n) \geq\left\lceil\frac{n}{2}\right\rceil-2$, for all $r \geq 2$ and $n \geq 3 r^{2}+1$. On the other hand, the characterization [10] of the graphs $G$ of order $n$ such that $i d_{1}(G)=n-1$ gives graphs which, apart from the star which is not the power of any graph, are such that $l d_{1}(G) \leq n-2$. This allows to conclude that $F_{l d, \gamma}(r, n) \leq n-3$. Indeed, $F_{l d, \gamma}(r, n)=n-2$ is possible only if a graph $G$ of order $n$ satisfies $\gamma_{r}(G)=1$ and $l d_{r}(G)=n-1$, which implies $\gamma_{1}\left(G^{r}\right)=1$ and $l d_{1}\left(G^{r}\right)=n-1=i d_{1}\left(G^{r}\right)$, contradicting the previous sentence.

Proposition 23. (a) For all $n \geq 3$, we have $F_{l d, \gamma}(1, n)=n-2$.
(b) For all $r \geq 2$ and $n \geq 3 r^{2}+1$, we have $F_{l d, \gamma}(r, n) \geq\left\lceil\frac{n}{2}\right\rceil-2$.
(c) For all $r \geq 2$ and $n \geq 2 r+1$, we have $F_{l d, \gamma}(r, n) \leq n-3$.

We now present a general framework using Theorem 5 in [6], and, to a lesser extent, Theorem 6 in [6], cf. Section 3, Proposition 11(a)-(b). We shall use it in the case $r=2$, when this gives a lower bound for $F_{l d, \gamma}(2, n)$ which is better than $\left\lceil\frac{n}{2}\right\rceil-2$, for all $n \geq 24$; for $r=3, n=30$, this gives no improvement, and we shall informally explain why for $r=3$ and larger $n$, or for larger $r$, this method is doomed to fail.

Let $m=2 p \geq 3 r^{2}+1$. We consider the Euclidean division of $p$ by $r$ : $p=r Q+R, 0 \leq R \leq r-1$, and set $k=Q+1, A=r-R$, so that $p=r k-A$ with $A \in\{1,2, \ldots, r\}$. We build $G_{m}=\left(V_{m}, E_{m}\right)$ in the following way:

$$
\begin{equation*}
V_{m}=\left\{v_{i}: 0 \leq i \leq m-1\right\} \tag{6}
\end{equation*}
$$

$$
\begin{equation*}
E_{m}=\left\{v_{i} v_{i+j \bmod m}: 0 \leq i \leq m-1, j \in J=\{1,2, \ldots, k-A-1, k\}\right\} \tag{7}
\end{equation*}
$$

The graph $G_{m}$ can be seen as a cycle with chords added according to the set $J$, where every vertex plays the same role, see Figure 5(a). Theorem 5 from [6] states that the $r$-th power of $G_{m}$ is the graph $G_{m}^{*}$ of Lemma 9 , with $m=2 p$. We now need to be more specific with respect to $r$.

In the case $r=2$, we can improve on Proposition $23(\mathrm{~b})$ and build, for $n$ large enough, graphs of order $n$ proving that $\frac{F_{l d, \gamma}(2, n)}{n}$ tends to $\frac{5}{8}$ when $n$ goes to infinity. The first step is the study of graphs with order a multiple of eight.

Proposition 24. For $n=8 t \geq 24$, there exists a 2 -twin-free graph $G_{n}$ of order $n$, with $\gamma_{2}\left(G_{n}\right)=2$ and $l d_{2}\left(G_{n}\right)=5 t-1$.

Proof. Let $m=6 t=2 p \geq 18$ and $p=2 k-A$ with $A \in\{1,2\}$. Because $A \in$ $\{1,2\}$ and $p \geq 9$, we have $p \geq 3 A+3 \Rightarrow p-A-1 \geq \frac{2 p}{3}=2 t \Rightarrow 2 k-2 A-1 \geq 2 t$, and finally

$$
\begin{equation*}
k-A \geq 2 t-(k-A-1) \tag{8}
\end{equation*}
$$

When $p=9$, then $A=1$ and $\frac{p}{3} \geq A+2$, which also holds whenever $p \geq 12$. Therefore, $\frac{2 k-A}{3} \geq A+2 \Rightarrow k \geq 2 A+3 \Rightarrow 3 k-3 A-3 \geq 2 k-A \Rightarrow k-A-1 \geq \frac{p}{3}$, and finally

$$
\begin{equation*}
2 t+k-A-1=\frac{2 p}{3}+k-A-1 \geq p \tag{9}
\end{equation*}
$$

These two inequalities, (8) and (9), will be used later on. We have already seen that the graph $G_{m}=\left(V_{m}, E_{m}\right)$ defined by (6) and (7) is such that the square power of $G_{m}$ is the graph $G_{m}^{*}$ of Lemma 9 , with $m=2 p$. This means that
$B_{G_{m}, 2}\left(v_{i}\right)=V_{m} \backslash\left\{v_{i+p \bmod m}\right\}$, for all $i \in\{0, \ldots, m-1\}$; in other words, from any $v_{i}$ we can go in two steps to any vertex in $V_{m}$ but $v_{i+p} \bmod m$. Next, we diverge from Theorem 6 in [6]: we add $\frac{m}{3}=2 t$ vertices $Z_{j}, 0 \leq j \leq 2 t-$ $1 ;$ every $Z_{j}$ is linked to three vertices in $V_{m}$, namely $v_{j}, v_{j+2 t}$ and $v_{j+4 t}$. By setting $G_{n}=\left(V_{n}, E_{n}\right)$ with $V_{n}=V_{m} \cup\left\{Z_{j}: 0 \leq j \leq 2 t-1\right\}$ and $E_{n}=$ $E_{m} \cup\left\{Z_{j} v_{j}, Z_{j} v_{j+2 t}, Z_{j} v_{j+4 t}: 0 \leq j \leq 2 t-1\right\}$, we obtain a graph of order $8 t$, see Figure 5(b).

Figure 5. (a) The graph $G_{m}$. (b) The graph $G_{n}(r=2)$. Not all vertices nor edges are represented. Only the indices of the vertices $v_{i}$ are given.

We claim that
(a) $B_{G_{n}, 2}\left(Z_{j}\right)=V_{m} \backslash\left\{Z_{\ell}: 0 \leq \ell \leq 2 t-1, \ell \neq j\right\}$, for all $j \in\{0, \ldots, 2 t-1\}$;
(b) $B_{G_{n}, 2}\left(v_{i}\right)=V_{m} \backslash\left\{v_{i+p} \bmod m\right\}$, for all $i \in\{0, \ldots, m-1\}$.
(a) That we cannot go in two steps from $Z_{j}$ to $Z_{\ell}$ is obvious since $B_{G_{n}, 1}\left(Z_{j}\right) \cap$ $B_{G_{n}, 1}\left(Z_{\ell}\right)=\emptyset$. Note already that this could not be directly transposed to the case $r \geq 3$, since then the existence of paths such as $Z_{j} v_{j}, v_{j} v_{j+1}, v_{j+1} Z_{j+1}$ would lead to a contradiction; see the discussion below for $r=3$.

Next, we show that we can go in two moves from any $Z_{j}$ to any $v_{i}$; because of the symmetries of the graph, we need to do it only for, say, $Z_{0}$, and the vertices going from $v_{0}$ to $v_{p}$. Thanks to the edge $Z_{0} v_{0}, Z_{0}$ can reach $v_{1}, v_{2}, \ldots, v_{k-1-A}$ (and $v_{k}$, but we do not need it) in two moves; thanks to the edge $Z_{0} v_{2 t}, Z_{0}$ can also reach $v_{2 t+1}, \ldots, v_{2 t+k-1-A}$ ( and $v_{2 t+k}$ ), as well as $v_{2 t-1}, \ldots, v_{2 t-(k-1-A)}$ (and $\left.v_{2 t-k}\right)$. Using (8), we can see that in the worst case, $v_{2 t-(k-1-A)}=v_{k-A}$ and all the vertices between $v_{0}$ and $v_{2 t}$ can be reached, including in particular $v_{k-1-A}$ and $v_{k-A}$. In other words, the areas reached in one move by going clockwise from $v_{0}$ or anticlockwise from $v_{2 t}$ do meet. Similarly, by (9), we have in the worst case $v_{2 t+k-A-1}=v_{p}$ and all the vertices between $v_{2 t+1}$ and $v_{p}$ can be reached in two moves from $Z_{0}$. Claim (a) is proved.
(b) The proof is the same as for the graph $G_{m}$; we just have to check that the additional vertices $Z_{j}$ and their edges do not make it possible to go in two moves from $v_{0}$ to $v_{p}$ (this is sufficient for reasons of symmetry).

Claims (a) and (b) show that $G_{n}$ is 2 -twin-free; they also show that the square power of $G_{n}$ is the following graph. $\left(G_{n}\right)^{2}$ has vertex set $V_{n}$ and edge set all the possible edges except the edges $v_{i} v_{i+p} \bmod m, 0 \leq i \leq p$, and $Z_{j} Z_{\ell},\{j, \ell\} \subset$ $\{0, \ldots, 2 t-1\}, j \neq \ell$, see Figure 6 .

Figure 6. A partial representation of $\left(G_{n}\right)^{2}$. Dotted lines are non-edges.
Now what are $\gamma_{1}\left(\left(G_{n}\right)^{2}\right)$ and $l d_{1}\left(\left(G_{n}\right)^{2}\right)$ (or equivalently, $\gamma_{2}\left(G_{n}\right)$ and $\left.l d_{2}\left(G_{n}\right)\right)$ ? Obviously, $\gamma_{1}\left(\left(G_{n}\right)^{2}\right)=2$. Next, the argument of Case (b) of the proofs of Lemmas 9 and 10 can be used to show that it is necessary to take half of the vertices $v_{i}$ in $V_{m}$ for a 2-LD code. Then, for $j \neq \ell$, we have $B_{\left(G_{n}\right)^{2}, 1}\left(Z_{j}\right) \Delta B_{\left(G_{n}\right)^{2}, 1}\left(Z_{\ell}\right)=\left\{Z_{j}, Z_{\ell}\right\}$, which implies that we have to take all vertices $Z_{j}$ but one as codewords, together with $p$ vertices in $V_{m}$, and this is sufficient, $l d_{1}\left(\left(G_{n}\right)^{2}\right)=p+(2 t-1)=5 t-1$.

In order to reach the values of $n$ other than multiples of eight, we might consider $m=6 t+2$ or $6 t+4$ instead of $m=6 t$, but it is more efficient to stick to $m=6 t$ and simply add a number of vertices $Z_{j}$ smaller (by a number between 1 and 7 ) than $2 t$. From $m=6 t \geq 18$ we constructed a graph with $8 t$ vertices; now, we start from $6(t+1)$, and, instead of building a graph with order $6(t+1)+2(t+1)=8(t+1)$, we build a graph with $6(t+1)+[2(t+1)-q]=8 t+(8-q)$ vertices, by adding only $2(t+1)-q$ vertices $Z_{j}$, with $1 \leq q \leq 7$. The resulting graph has its 2-domination number equal to 1 (in the unique case when $t=3, q=7$ and we add only one vertex, $Z_{0}$ ) or 2 ; any minimum 2-LD code has size $3(t+1)+[2(t+1)-q-1]=$ $5(t+1)-q-1$, including when $2(t+1)-q=1$.

So, letting $i=8-q, 1 \leq i \leq 7$, we obtain graphs $G_{n}$ with order $n=8 t+i$ and $l d_{2}\left(G_{n}\right)=5 t+i-4$ (the borderline case $i=0$, i.e., dropping eight vertices $Z_{j}$, logically leads to a worse result, namely $5 t-4$, than if we start from $6 t$ to reach $8 t$, in which case we have just seen that we obtain $5 t-1$ ). Since the 2 -domination number of these graphs is at most 2 , we have the following result.

Proposition 25. (a) Let $n=8 t \geq 24$. Then $F_{l d, \gamma}(2, n) \geq 5 t-3$.
(b) Let $n=8 t+i \geq 24$, with $1 \leq i \leq 7$. Then $F_{l d, \gamma}(2, n) \geq 5 t+i-6$.

The least favorable case is when $i=1$, which leads to

$$
\begin{equation*}
F_{l d, \gamma}(2, n) \geq \frac{5 n-45}{8} \tag{10}
\end{equation*}
$$

The case $m=6 t$ works best because we have a miraculously large number of $Z_{j}$ 's, namely $2 t$, which is advantageous when we look for a "large" LD-code, since we have to take all of them but one in a 1-LD code in $\left(G_{n}\right)^{2}$. If we consider $m=6 t+2$ or $m=6 t+4$, we cannot take as many vertices $Z_{j}$; yet, if we can take a number of $Z_{j}$ 's which is only a fraction $\frac{m}{\beta}$ with $\beta>3$, then we obtain a graph $G_{n}$ with order $n=m+\frac{m}{\beta}$ and $l d_{2}\left(G_{n}\right)=l d_{1}\left(\left(G_{n}\right)^{2}\right)=\frac{m}{2}+\frac{m}{\beta}-1$, leading to the ratio $\frac{F_{l d, \gamma}(2, n)}{n}$ greater than $\frac{l d_{2}\left(G_{n}\right)-2}{n} \approx \frac{\beta+2}{2 \beta+2}$, which is not as good as $\frac{5}{8}$.

For $r=3$, we consider $m=30=2 p=2(3 k-A)$, leading to $p=15, k=6$, $A=3, J=\{1,2,6\}$. To the graph $G_{30}$ defined by (6) and (7), whose third power, by [6, Theorem 5], is $G_{30}^{*}$, we add first the vertex $Z_{0}$ together with the edges $Z_{0} v_{0}, Z_{0} v_{10}$ and $Z_{0} v_{20}$. Then we add the vertex $Z_{1}$. Because we want no path of the type $Z_{0} v_{0} v_{i} Z_{1}$ for some $i$, among the vertices $\left\{v_{1}, \ldots, v_{15}\right\}, Z_{1}$ cannot be linked to $v_{1}, v_{2}$ nor $v_{6}$; because of $Z_{0} v_{10}$, this also excludes $v_{4}, v_{8}, v_{9}, v_{11}$ and $v_{12}$ as neighbours of $Z_{1}$. Finally we can take, e.g., $Z_{1}$ with the edges $Z_{1} v_{3}, Z_{1} v_{13}$, $Z_{1} v_{23}, Z_{2}$ with $Z_{2} v_{7}, Z_{2} v_{17}, Z_{2} v_{27}$, and no more. Exactly as before, this leads to a graph $G_{33}$ whose third power is a graph of the type given by Figure 6, with 33 vertices, $l d_{3}\left(G_{33}\right)=15+(3-1)=17,3$-domination number equal to 2 , and $l d_{3}\left(G_{33}\right)-\gamma_{3}\left(G_{33}\right)=15=\left\lceil\frac{33}{2}\right\rceil-2$, i.e., not better than Proposition $23(\mathrm{~b})$.

It is impossible to take fewer than three neighbours for each vertex $Z_{\ell}$. On the other hand, as discussed above when studying the possible neighbours of $Z_{1}$, if $v_{0}$ is the neighbour of $Z_{0}$, the "first" neighbour of $Z_{1}$ will be $v_{i}$ with $i \geq k-A$, for $Z_{2}$ it will be $v_{j}$ with $j \geq i+(k-A) \geq 2(k-A), \ldots$ So, roughly speaking, the total number of possible neighbours for the vertices $Z_{\ell}$ is at most

$$
\begin{equation*}
\frac{m}{k-A}=\frac{m}{\frac{p}{3}-\frac{2 A}{3}}=\frac{6 p}{p-2 A} \tag{11}
\end{equation*}
$$

and therefore, the number of vertices $Z_{\ell}$ is at most $\frac{2 p}{p-2 A}$. When $p=15$, this leads to at most three vertices $Z_{\ell}$, and things only worsen when $m$, hence $p$ increases. Anyway, with only three additional vertices $Z_{\ell}$, all we can reach is a graph $G_{n}$ with $n=m+3$ vertices and

$$
l d_{3}\left(G_{n}\right)-\gamma_{3}\left(G_{n}\right)=(p+(3-1))-2=p=\frac{n-3}{2}
$$

Figure 7. (a) $n$ odd: $n=2 k+1 \geq 5$. (b) $n$ even: $n=2 k+2 \geq 8$. The $k$ black vertices represent codewords constituting both a minimum 1-dominating and 1-locatingdominating code.

When we place ourselves again in the general case for $r$, we must have the "first" neighbour of $Z_{1}$, say $v_{i}$, such that $i \geq(r-2)(k-A)$, in order to avoid a path of length $r$ between $Z_{0}$ and $Z_{1}$, and equalities (11) now read

$$
\frac{m}{(r-2)(k-A)}=\frac{m}{(r-2)\left(\frac{p}{r}-\frac{(r-1) A}{r}\right)}=\frac{2 r p}{(r-2)(p-(r-1) A)}
$$

Even with $p=\frac{3 r^{2}}{2}$ and $A=r$, this can lead only to approximately $\frac{3 r^{3}}{(r-2) \frac{r^{2}}{2}} \approx 6$, hence at most two vertices $Z_{\ell}$, and again, things only worsen when $p$ increases. Therefore, other constructions should be invented-that is, if improvements do exist in Proposition 23(b).

Open Problem. Reduce the gap between lower and upper bounds for $F_{l d, \gamma}(r, n)$, when $r>1$.

### 7.2. Graphs with twins

The study of $F_{l d, \gamma}^{t w}(r, n)$ is trivial, because of the clique, or complete graph on $n$ vertices, $K_{n}$, which obviously contains $r$-twins, and is such that $\gamma_{r}\left(K_{n}\right)=1$ and $l d_{r}\left(K_{n}\right)=n-1$.

We are going to prove that (i) for $r=1$ and $n \in\{2,5\}$ or $n \geq 7$ (Proposition 26) and (ii) for any $r \geq 2$ and $n$ large enough (Proposition 28), we have $f_{l d, \gamma}^{t w}(r, n)=0$.

Proposition 26. (a) For $n=2, n=5$ and all $n \geq 7$, we have $f_{l d, \gamma}^{t w}(1, n)=0$;
(b) For $n \in\{3,4,6\}$, we have $f_{l d, \gamma}^{t w}(1, n)=1$.

Proof. We already know by Proposition 12(a) that

$$
f_{l d, \gamma}^{t w}(1,2)=0 ; f_{l d, \gamma}^{t w}(1,3)=1 ; f_{l d, \gamma}^{t w}(1,4)=1
$$

For $n=6$, Lemma 1(a) and Proposition 5(a) state that for any connected graph $G$ with six vertices, $l d_{1}(G) \geq 3$ and $\gamma_{1}(G) \leq 3$; but a study of the graphs
with 1-twins shows that for them, $\gamma_{1}(G) \leq 2$ (alternatively, one can use the characterization of the graphs with even order and 1-domination number half their order [13, p. 42], $[9,17]$ ), and eventually $f_{l d, \gamma}^{t w}(1,6)=1$. For $n=5$ and $n \geq 7$, we consider the graphs in Figure 7, obtained from the graphs in Figure 4 by a slight modification, intended to create one pair of 1-twins. The study of these graphs is straightforward and gives the desired result.

We now turn to the case $r \geq 2$ (even if the results below are also valid for $r=1$ ); first, we give an analogue of Proposition 13 for $r$-LD codes. We take the graphs $G_{n}^{*}=\left(V_{n}^{*}, E_{n}^{*}\right)$ represented in Figure 3(a) and described just before Proposition 13, and transform them into graphs $G_{n+1}^{y}$ by applying the same type of modification just performed for $r=1$. We simply add one vertex $y$ which is the $r$-twin of $v_{k, r}$, see Figure 8(a). The order of $G_{n+1}^{y}$ is $n+1=k(r+1)+1$.

Figure 8. The $k$ black vertices represent codewords.
Observation 27. Because here we deal with r-LD codes, not r-ID codes like in Proposition 13, the bound for $k$ could be lowered, down to $k \geq 2 r$. For simplicity and because this does not represent a significant improvement, we keep the bound $k \geq 2 r+2$.
Proposition 28. For all $r \geq 2$ and $k \geq 2 r+2$, the graphs $G_{n+1}^{y}$ are such that $\gamma_{r}\left(G_{n+1}^{y}\right)=l d_{r}\left(G_{n+1}^{y}\right)$.
Proof. Obviously, $k \leq \gamma_{r}\left(G_{n+1}^{y}\right)$ (and $\left.k \leq l d_{r}\left(G_{n+1}^{y}\right)\right)$, and the code $C=\left\{v_{1,0}\right.$, $\left.v_{2,0}, \ldots, v_{k-1,0}, y\right\}$, with $k$ codewords, is an $r$-D code. We are going to prove that $C$ is also $r$-LD. In spite of the fact that all we have to check is that any two distinct non-codewords are $r$-separated by $C$, the proof is a little more intricate than the proof of Proposition 13 for $r$-ID codes, because of the "missing" codeword $v_{k, 0}$, so we present it in detail.
(a) The non-codewords $v_{k, j}, 0 \leq j \leq r$, are the only non-codewords $r$ dominated by $y$, so they all are $r$-separated by $y \in C$ from other non-codewords; each of them is $r$-dominated by a different number of codewords, because $k$ is large enough, and therefore they are pairwise $r$-separated by $C$.
(b) Consider any two non-codewords $v_{i, j}, v_{i, t}$ on the same string $i, 1 \leq i \leq$ $k-1,\{j, t\} \subseteq\{1, \ldots, r\}, j<t$; then $v_{i, j}$ is $r$-dominated by at least one codeword more than $v_{i, t}$ (it would be at least two if we had all $k$ elements of the cycle in the code), and so these two vertices are $r$-separated by $C$.
(c) Let us consider two non-codewords $v_{i, j}$ and $v_{s, t}$ belonging to two different strings, other than the $k$-th string: $\{i, s\} \subset\{1, \ldots, k-1\}, i \neq s,\{j, t\} \subseteq$ $\{1, \ldots, r\}$; without loss of generality, we may assume that $j \leq t$.

If $j<t$, then again, $v_{i, j}$ is $r$-dominated by at least one codeword more than $v_{s, t}$; so from now on, we assume that $j=t$. The set of codewords $r$-dominating $v_{i, j}$ has cardinality $2 r-2 j+1$ or $2 r-2 j$, and consists, with computations performed modulo $k$, of $v_{i, 0}, v_{i-1,0}, \ldots, v_{i-r+j, 0}, v_{i+1,0}, \ldots, v_{i+r-j, 0}$, or of the same set without $v_{k, 0}$, which is not a codeword. In both cases, it cannot be the same as the set of codewords $r$-dominating $v_{s, j}$.
We have just proved that $C r$-separates the non-codewords $v_{k, j}$ between themselves and from the other non-codewords; the non-codewords belonging to the same string; the non-codewords belonging to different strings. Therefore $C$ is an $r$-LD code.

Now, like in Proposition 14, we want to reach all intermediate values between $k(r+1)+1$ and $(k+1)(r+1)$. We do so by adding a set $W_{p}=\left\{w_{1}, \ldots, w_{p}\right\}$ of $p$ vertices, $p \in\{0, \ldots, r\}$. However, if we proceed exactly as for Proposition 14 by creating the edge set $X_{p}=\left\{w_{1} v_{1,0}, w_{1} v_{2,0}, w_{2} v_{3,0}, w_{2} v_{4,0}, \ldots, w_{p} v_{2 p-1,0}, w_{p} v_{2 p, 0}\right\}$ but now considering the code $C=\left\{v_{1,0}, \ldots, v_{k-1,0}\right\} \cup\{y\}$, we might have one or two pairs of vertices not $r$-separated by $C$. We show one such pair ( $v_{4,1}$ and $w_{2}$ ) in Figure 9 when $r=4, k=11, p=4$; more generally, this may occur whenever $r$ is even. Moreover, a symmetrical situation appears when $k-r$ is odd, see the same Figure with $w_{4}$ and $v_{7,1}$. The existence of both pairs is due to the fact that $v_{k, 0} \notin C$.

So we choose another way of linking the vertices $w_{i}$ to the vertices $v_{s, 0}: X_{p}=$ $\left\{w_{1} v_{1,0}, w_{1} v_{3,0}, w_{2} v_{2,0}, w_{2} v_{4,0}, \ldots\right\}$, see Figure 8(b) for $p=2$. Setting $G_{n+1+p}^{y}=$ $\left(V_{n}^{*} \cup\{y\} \cup W_{p}, E_{n}^{*} \cup\left\{y v_{k, r}, y v_{k, r-1}\right\} \cup X_{p}\right)$, we obtain a graph of order $n+1+p=$ $k(r+1)+1+p$.
Proposition 29. For all $r \geq 2, k \geq 2 r+2$ and $p \in\{0, \ldots, r\}$, the graph $G_{k(r+1)+1+p}^{y}$ is such that $\gamma_{r}\left(G_{k(r+1)+1+p}^{y}\right)=l d_{r}\left(G_{k(r+1)+1+p}^{y}\right)$.
Proof. Again, we take $C=\left\{v_{i, 0}: 1 \leq i \leq k-1\right\} \cup\{y\}$. Using anew the proof of the previous proposition, we can see that we have only to prove in addition the following two assertions about the $w_{i}$ 's.
(a) If $p \geq 2$, any two non-codewords $w_{i}$ and $w_{s},\{i, s\} \subseteq\{1,2, \ldots, p\}, i<s$, are $r$-separated by $C$. If $w_{i}$ is linked to $v_{\ell, 0}$ and $v_{\ell+2,0}$, then the set of codewords $r$ dominating $w_{i}$ has size $3+2(r-1)$ or $2+2(r-1)$, and consists (with computations
modulo $k$ ) of $v_{\ell, 0}, v_{\ell+1,0}, v_{\ell+2,0}, v_{\ell-1,0}, \ldots, v_{\ell-r+1,0}, v_{\ell+3,0}, \ldots, v_{\ell+2+r-1,0}$, or of the same set without $v_{k, 0}$. In both cases, it cannot be the same as the set of codewords $r$-dominating $w_{s}$.

Figure 9. $r=4, n=60$. The eleven black vertices represent codewords. Not all strings are shown. The vertices $w_{2}$ and $v_{4,1}$ are not 4 -separated by $C$; neither are $w_{4}$ and $v_{7,1}$, which are both 4 -dominated by $v_{i, 0}, 4 \leq i \leq 10$, as indicated by the dotted-line box.
(b) Two non-codewords $w_{i}, i \in\{1, \ldots, p\}$, and $v_{s, t}, 1 \leq s \leq k-1,1 \leq t \leq r$, are $r$-separated by $C$. If $w_{i}$ is linked to $v_{\ell, 0}$ and $v_{\ell+2,0}$, the most crucial cases are when $s \in\{\ell, \ell+1, \ell+2\}$ and $t=1$, but even here, $w_{i}$ is $r$-dominated by more codewords than $v_{s, 1}$ (note that this "W-construction" would not have worked for $r$-ID codes, because then $w_{i}$ and $v_{\ell+1,0}$ would not be $r$-separated by the code).

Corollary 30. For all $r \geq 2$ and $n \geq(2 r+2)(r+1)+1$, we have $f_{l d, \gamma}^{t w}(r, n)=0$.

## 8. Conclusion

In the following tables, we recapitulate our results on the different minimum and maximum differences between cardinalities of minimum dominating, locatingdominating or identifying codes in connected graphs, first for $r=1$, then for $r \geq 2$. For $r=1$, we have exact values for all $n$ and all functions.

| $n$ | 2 | 3 | 4 | 5 | 6 | $\geq 7$ | Proposition |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $f_{i d, \gamma}(1, n)$ | $\times$ | 1 | 1 | 1 | 0 | 0 | 16 |
| $F_{i d, \gamma}(1, n)$ | $\times$ | 1 | 2 | 3 | 4 | $n-2$ | 17 |
| $f_{i d, l d}(1, n)$ | $\times$ | 0 | 0 | 0 | 0 | 0 | 19 |
| $F_{i d, l d}(1, n)$ | $\times$ | 0 | 1 | 2 | 2 | $\left\lceil\frac{n}{2}\right\rceil-1$ | 21 |
| $f_{l d, \gamma}(1, n)$ | $\times$ | 1 | 0 | 0 | 0 | 0 | $22(\mathrm{a})-(\mathrm{b})$ |
| $F_{l d, \gamma}(1, n)$ | $\times$ | 1 | 2 | 3 | 4 | $n-2$ | $23(\mathrm{a})$ |
| $f_{l,}^{t w}(1, n)$ | 0 | 1 | 1 | 0 | 1 | 0 | 26 |
| $F_{l d, \gamma}^{t w}(1, n)$ | 0 | 1 | 2 | 3 | 4 | $n-2$ | (clique) |

For $r \geq 2$, most results are valid for $n$ large (typically, $n$ is in $r^{2}$ ).

| $i d$ vs $\gamma$ | $\forall r \geq 2, f_{i d, \gamma}(r, n)=0$ [Proposition 14] |
| :---: | :--- |
|  | $n$ even, $\forall r \geq 2, F_{i d, \gamma}(r, n)=n-3$ [Proposition 18(a)] |
|  | $n$ odd, $\forall r \geq 2, F_{i d, \gamma}(r, n)=n-2$ [Proposition 18(b)] |
| $i d$ vs $l d$ | $\forall r \geq 2, f_{i d, l d}(r, n)=0$ [Corollary 15] |
|  | $\forall r \geq 2, F_{i d, l d}(r, n)=\left[\frac{n}{2}\right]-1$ [Proposition 20] |
| $l d$ vs $\gamma$ | $\forall r \geq 2, f_{l d, \gamma}(r, n)=0$ [Corollary 15, Proposition 22(c)] |
| (twin-free | $F_{l d, \gamma}(2, n) \geq \frac{5 n-45}{8} \approx \frac{5 n}{8}$ [Prop. 25(b), case $i=1$, ineq. (10)] |
| graphs) | $\forall r \geq 3, F_{l d, \gamma}(r, n) \geq\left[\frac{n}{2}\right\rceil-2$ [Proposition 23(b)] |
|  | $\forall r \geq 2, F_{l l, \gamma}(r, n) \leq n-3$ [Proposition 23(c)] |
| $l d$ vs $\gamma$ | $\forall r \geq 2, f_{l d, \gamma}^{t t w}(r, n)=0$ [Corollary 30] |
| (with twins) | $\forall r \geq 2, F_{l d, \gamma}^{t w}(r, n)=n-2$ (clique) |
