#### Abstract

Let $\operatorname{odd}(G)$ denote the number of odd components of a graph $G$ and $k \geq 2$ be an integer. We give sufficient conditions using $\operatorname{odd}(G-S)$ for a graph $G$ to have an even factor. Moreover, we show that if a graph $G$ satisfies odd $(G-S) \leq \max \{1,(1 / k)|S|\}$ for all $S \subset V(G)$, then $G$ has a ( $k-1$ )-regular factor for $k \geq 3$ or an $\mathbf{H}$-factor for $k=2$, where we say that $G$ has an $\mathbf{H}$-factor if for every labeling $h: V(G) \rightarrow$ \{red, blue $\}$ with $\#\{v \in V(G): f(v)=$ red $\}$ even, $G$ has a spanning subgraph $F$ such that $\operatorname{deg}_{F}(x)=1$ if $h(x)=$ red and $\operatorname{deg}_{F}(x) \in\{0,2\}$ otherwise.

Keywords: factor of graph, even factor, regular factor, Tutte type condition.
2010 Mathematics Subject Classification: 05C70.

[^0]
## 1. Introduction

In this paper we consider finite graphs which have neither multiple edges nor loops. For a graph $G$, let $V(G)$ and $E(G)$ denote the set of vertices and the set of edges of $G$, respectively. We write $|G|$ for the order of $G$ (i.e., $|G|=|V(G)|$ ). For a vertex $v$ of $G$, we denote by $\operatorname{deg}_{G}(v)$ the degree of $v$ in $G$. The minimum degree of $G$ is denoted by $\delta(G)$. An edge of $G$ joining a vertex $u$ to a vertex $v$ is denoted by $u v$ or $v u$. For a subset $S$ of $V(G)$, we write $G-S$ for the subgraph of $G$ induced by $V(G) \backslash S$. Let $\operatorname{odd}(G)$, iso $(G)$ and $\omega(G)$ denote the number of odd components of $G$ (i.e., components of $G$ of odd order) the number of isolated vertices of $G$, and the number of components of $G$, respectively. The complete graph, the path and the cycle of order $n$ are denoted by $K_{n}, P_{n}$ and $C_{n}$, respectively. The complete bipartite graph with parts of sizes $m$ and $n$ is denoted by $K_{m, n}$. In particular, $K_{2}=P_{2}$ and $K_{1,2}=P_{3}$. For a set $X$, the cardinality of $X$ is denoted by $|X|$ or $\# X$. Other notation and definitions not defined in this paper are standard and found in the book [14].

We give some definitions of factors of graphs. Let $G$ be a graph and $F$ be its spanning subgraph. Then for a set $\mathcal{S}$ of connected graphs, $F$ is called an $\mathcal{S}$-factor of $G$ if every component of $F$ is isomorphic to an element of $\mathcal{S}$. For a set $\mathbb{S}$ of positive integers, $F$ is called an $\mathbb{S}$-factor of $G$ if $\operatorname{deg}_{F}(x) \in \mathbb{S}$ for all $x \in V(G)$. For an integer $k \geq 1, F$ is called a $k$-regular factor or a $k$-factor of $G$ if $\operatorname{deg}_{F}(x)=k$ for all $x \in V(G)$. For a function $f: V(G) \rightarrow\{1,3,5, \ldots\}, F$ is called an $(1, f)$-odd factor of $G$ if $\operatorname{deg}_{F}(x) \in\{1,3, \ldots, f(x)\}$ for all $x \in V(G)$. A $\{2,4,6, \ldots\}$-factor is called an even factor. So every vertex of an even factor $F$ has a positive even degree in $F$.

We now present some known results on factors of graphs related to our theorems.

Theorem 1. Let $G$ be a graph. Then the following statements hold.

1. $G$ has a 1-factor if and only if odd $(G-S) \leq|S|$ for all $S \subset V(G)$, (Tutte [12]).
2. Let $n \geq 3$ be an odd integer. Then $G$ has a $\{1,3, \ldots, n\}$-factor if and only if odd $(G-S) \leq n|S|$ for all $S \subset V(G)$, (Amahashi [1]).
3. Let $f: V(G) \rightarrow\{1,3,5, \ldots\}$. Then $G$ has a $(1, f)$-odd factor if and only if odd $(G-S) \leq \sum_{x \in S} f(x)$ for all $S \subset V(G)$, (Cui and Kano [4]).
4. Let $m \geq 2$ be an even integer. Then $G$ has a $\{1,3, \ldots, m-1, m\}$-factor if odd $(G-S) \leq m|S|$ for all $S \subset V(G),($ Lu and Wang [10]).

On the other hand, the following theorem shows some results on factors of graphs $G$ which satisfy certain conditions on $i s o(G-S)$ instead of $\operatorname{odd}(G-S)$.

Theorem 2. Let $G$ be a graph. Then the following statements hold.

1. $G$ has a $\left\{K_{2}, C_{n}: n \geq 3\right\}$-factor if and only if iso $(G-S) \leq|S|$ for all $S \subset V(G),($ Tutte [13]).
2. Let $n \geq 2$ be an integer. Then $G$ has a $\left\{K_{1,1}, K_{1,2}, \ldots, K_{1, n}\right\}$-factor if and only if iso $(G-S) \leq n|S|$ for all $S \subset V(G)$, (Amahashi and Kano [2], Las Vergnas [8]).
3. If iso $(G-S) \leq(1 / 2)|S|$ for all $S \subset V(G)$, then $G$ has a $\left\{K_{1,2}, K_{1,3}, K_{5}\right\}$ factor, (Kano, Lu and Yu [6]).
4. Let $m \geq 2$ be an integer. If iso $(G-S) \leq(1 / m)|S|$ for all $S \subset V(G)$, then $G$ has a $\left\{K_{1, m}, K_{1, m+1}, \ldots, K_{1,2 m}\right\}$-factor, (Kano and Saito [7]).
5. Let $m \geq 2$ be an integer. If iso $(G-S) \leq(1 / m)|S|$ for all $S \subset V(G)$, then $G$ has a $\left\{K_{1, m}, K_{1, m+1}, \ldots, K_{1,2 m-1}, K_{2 m+1}\right\}$-factor, (Zhang, Yan and Kano [15]).

Proofs of the most results given in Theorems 1 and 2 and some other results on factors can be found in the book [3] by Akiyama and Kano. In this paper, we consider the following problem.

Problem 3. Suppose that a graph $G$ satisfies $\operatorname{odd}(G-S) \leq \max \{1, \alpha|S|\}$ or $\operatorname{odd}(G-S)<\max \{2, \alpha|S|\}$ for all $S \subset V(G)$ and for a rational number $0<\alpha \leq 1$. What kind of a factor does $G$ have?

Notice that if a graph $G$ has even order and $0<\alpha<1$, then for a vertex $v$ of $G, \operatorname{odd}(G-v) \geq 1$ and $\alpha|\{v\}|<1$, and so odd $(G-S) \leq \alpha|S|$ does not hold. Hence we need the condition $\operatorname{odd}(G-S) \leq \max \{1, \alpha|S|\}$ or $\operatorname{odd}(G-S)<\max \{2, \alpha|S|\}$ instead of $\operatorname{odd}(G-S) \leq \alpha|S|$.

As shown in Theorem 2, for some rational numbers $0<\alpha<1$, there are some results on factors of graphs which satisfy $i s o(G-S) \leq \alpha|S|$ for all $S \subset V(G)$. On the other hand, there are no known results concerning Problem 3. We provide some partial solutions of this problem in Theorems 4 and 5.

Theorem 4. Let $G$ be a graph with $|G| \geq 3$. If $G$ satisfies one of the following conditions (i) and (ii), then $G$ has an even factor.
(i) $G$ is of even order and satisfies

$$
\begin{equation*}
\operatorname{odd}(G-S)<|S| \quad \text { for all } \quad S \subset V(G) \text { with }|S| \geq 2 . \tag{1}
\end{equation*}
$$

(ii) $G$ is of odd order and satisfies

$$
\begin{equation*}
\operatorname{odd}(G-S)<\frac{2}{3}|S| \quad \text { for all } \quad \emptyset \neq S \subset V(G) . \tag{2}
\end{equation*}
$$

We remark that if $G$ is of even order, then the condition (1) is equivalent to

$$
\begin{equation*}
\operatorname{odd}(G-S)<\max \{2,|S|\} \quad \text { for all } \quad S \subset V(G) . \tag{3}
\end{equation*}
$$

It is obvious that (1) and (3) are equivalent for $S \subset V(G)$ with $|S| \geq 2$. So we consider the case when $S$ consists of one vertex $v$. It suffices to show that (1) implies $\operatorname{odd}(G-v) \leq 1$. Assume that $\operatorname{odd}(G-v)>1$. Then $\operatorname{odd}(G-v) \geq 3$ since $G$ is of even order. Take a vertex $u$ from an odd component of $G-v$, then $\operatorname{odd}(G-\{v, u\}) \geq 2$. This contradicts (1). Hence (1) implies odd $(G-v) \leq 1$, and thus (1) and (3) are equivalent.

Theorem 5. Let $k \geq 3$ be an integer, and $G$ be a connected graph with $|G| \geq k$. If $(k-1)|G|$ is even and $G$ satisfies

$$
\begin{equation*}
\operatorname{odd}(G-S) \leq \max \left\{1, \frac{1}{k}|S|\right\} \quad \text { for all } \quad S \subset V(G) \tag{4}
\end{equation*}
$$

then $G$ has a $(k-1)$-regular factor.
Theorem 6. Let $G$ be a connected graph of order at least 2. If

$$
\begin{equation*}
\operatorname{odd}(G-S) \leq \max \left\{1, \frac{1}{2}|S|\right\} \quad \text { for all } \quad S \subset V(G), \tag{5}
\end{equation*}
$$

then for every vertex-labeling $h: V(G) \rightarrow\{$ red, blue $\}$ with $\#\{v \in V(G): h(v)=$ red\} even, $G$ has a spanning subgraph $F$ such that

$$
\begin{equation*}
\operatorname{deg}_{F}(v)=1 \quad \text { if } \quad h(v)=\text { red, } \quad \text { and } \quad \operatorname{deg}_{F}(v) \in\{0,2\} \quad \text { otherwise. } \tag{6}
\end{equation*}
$$

Notice that if for every $h: V(G) \rightarrow\{$ red, blue $\}$ with $\#\{v \in V(G): h(v)=$ red\} even, $G$ has a spanning subgraph $F$ satisfying (6), then we say that $G$ has an $\mathbf{H}$-factor [9]. Moreover, the spanning subgraph $F$ that satisfies (6) and has a minimal edge set consists of vertex disjoint paths which connect two red vertices and whose all inner vertices are blue. We conclude this section by showing that the conditions of Theorem 4 are best possible in some sense.

Example 7. We show that the condition (1) of Theorem 4 cannot be replaced by odd $(G-S) \leq|S|$ for all $S \subset V(G)$ with $|S| \geq 2$. Let $k \geq 2$ be an integer, and let $C_{2 k}$ and $C_{2 k-1}$ be the cycles of order $2 k$ and $2 k-1$, respectively. We construct the graph $G_{1}$ from $C_{2 k}$ and $C_{2 k-1}$ by adding a new vertex $v$ together with two edges $v u_{1}, v u_{2}$, where $u_{1} \in V\left(C_{2 k}\right)$ and $u_{2} \in V\left(C_{2 k-1}\right)$. Then $G_{1}$ is of even order and has no even factor. On the other hand, $G_{1}$ has a 1 -factor, and so by the 1 -factor theorem (1. of Theorem 1 ), $G_{1}$ satisfies $\operatorname{odd}\left(G_{1}-S\right) \leq|S|$ for all $S \subset V\left(G_{1}\right)$. Hence the condition (1) is best possible.

In order to show the sharpness of condition (2) of Theorem 4, we need the following theorem. Here for a component $C$ of $G-S$ with $S \subset V(G)$, the number of edges of $G$ joining $C$ to $S$ is denoted by $e_{G}(C, S)$.

Lemma 8 (Theorem 6.2 of [3]). A connected graph $G$ has an even factor if and only if

$$
\sum_{x \in S}\left(\operatorname{deg}_{G}(x)-2\right)-q(G, S) \geq 0 \quad \text { for all } \quad S \subset V(G)
$$

where $q(G, S)$ denotes the number of components $C$ of $G-S$ such that $e_{G}(C, S) \equiv$ $1(\bmod 2)$.

Example 9. We next show that the condition (2) of Theorem 4 cannot be replaced by the condition that $\operatorname{odd}(G-S) \leq(2 / 3)|S|$ for all $\emptyset \neq S \subset V(G)$. Let $n \geq 3$ be an integer, $D_{1}$ and $D_{2}$ be the complete graphs of order $2 n+1$, and $Z=\left\{z_{1}, z_{2}, \ldots, z_{5}\right\}$ be a set of 5 vertices. Let us take 10 vertices $u_{i} \in V\left(D_{1}\right), v_{i} \in$ $V\left(D_{2}\right)$ for $1 \leq i \leq 5$, and define the graph $G_{2}$ by

$$
\begin{aligned}
& V\left(G_{2}\right)=V\left(D_{1}\right) \cup V\left(D_{2}\right) \cup Z \quad \text { (disjoint union), and } \\
& E\left(G_{2}\right)=E\left(D_{1}\right) \cup E\left(D_{2}\right) \cup\left\{z_{i} u_{i}, z_{i} v_{i}: 1 \leq i \leq 5\right\} .
\end{aligned}
$$

Then $G_{2}$ has odd order. Consider $S_{1}=\left\{u_{i}, v_{i}, z_{5}: 1 \leq i \leq 4\right\}$. Then we have $\operatorname{odd}\left(G_{2}-S_{1}\right)=6=(2 / 3)\left|S_{1}\right|$ and for other $\emptyset \neq S \subset V\left(G_{2}\right)$, we can easily show that odd $\left(G_{2}-S\right)<(2 / 3)|S|$. Thus,

$$
\operatorname{odd}\left(G_{2}-S\right) \leq \frac{2}{3}|S| \quad \text { for all } \quad \emptyset \neq S \subset V\left(G_{2}\right) .
$$

Since $\sum_{x \in Z}\left(\operatorname{deg}_{G}(x)-2\right)-q(G, Z)=-2$, Lemma 8 implies that $G_{2}$ has no even factor. Hence the condition (2) is also best possible.

## 2. Proof of Theorem 4

In this section we prove Theorem 4. We need the following result.
Lemma 10 (Problem 42 in Section 7 of [11], Theorem 6.3 of [3]). Every 2-edge connected graph $G$ with $\delta(G) \geq 3$ has an even factor.

We now prove Theorem 4.
Proof of Theorem 4 under the condition (i). Assume that a graph $G$ satisfies the condition (i). Then $|G|$ is even and $|G| \geq 4$.
Claim 1. $G$ is connected.

Proof. Assume that $G$ is not connected. Let $G=H_{1} \cup H_{2} \cup \cdots \cup H_{m}$ be the decomposition of $G$ into its components, where $m \geq 2$. We first assume that two components, say $H_{1}$ and $H_{2}$, are of even order. Take two vertices $v_{1} \in V\left(H_{1}\right)$ and $v_{2} \in V\left(H_{2}\right)$. Then $2 \leq \operatorname{odd}\left(G-\left\{v_{1}, v_{2}\right\}\right)<\left|\left\{v_{1}, v_{2}\right\}\right|=2$, a contradiction. Hence at most one of components $H_{i}$ has even order.

If a component $H_{a}$ has even order, then at least two components have odd order and so $m \geq 3$. Take two vertices $v_{3}, v_{4} \in V\left(H_{a}\right)$. Then $2 \leq \operatorname{odd}(G-$ $\left.\left\{v_{3}, v_{4}\right\}\right)<\left|\left\{v_{3}, v_{4}\right\}\right|=2$, a contradiction. Hence every component $H_{i}$ has odd order. If a component $H_{b}$ has order at least 3 , then take two vertices $v_{5}, v_{6} \in$ $V\left(H_{b}\right)$. Then $2 \leq m \leq \operatorname{odd}\left(G-\left\{v_{5}, v_{6}\right\}\right)<\left|\left\{v_{5}, v_{6}\right\}\right|=2$, a contradiction. Hence every component $H_{i}$ has order 1. It follows from $m=|G| \geq 4$ that $2 \leq m-2 \leq \operatorname{odd}\left(G-V\left(H_{1}\right) \cup V\left(H_{2}\right)\right)<\left|V\left(H_{1}\right) \cup V\left(H_{2}\right)\right|=2$, a contradiction. Therefore $G$ is connected.

Claim 2. $G$ is 2-edge connected.
Proof. Assume that $G$ is not 2-edge connected. Then there exists an edge $e \in$ $E(G)$ such that $G-e$ consists of two components $D_{1}$ and $D_{2}$. Let $e=v_{1} v_{2}$ and $v_{1} \in V\left(D_{1}\right), v_{2} \in V\left(D_{2}\right)$. Since $|G|$ is even, we have $\left|D_{1}\right| \equiv\left|D_{2}\right|(\bmod 2)$. If $\left|D_{1}\right|$ is even, then $2 \leq \operatorname{odd}\left(G-\left\{v_{1}, v_{2}\right\}\right)<\left|\left\{v_{1}, v_{2}\right\}\right|=2$, a contradiction. If $\left|D_{1}\right|$ is odd, then $\left|D_{2}\right|$ is odd, and so by symmetry and by $|G| \geq 4$, we may assume that $\left|D_{1}\right| \geq 3$. Take one vertex $v_{3} \in V\left(D_{1}\right)$ and $v_{3} \neq v_{1}$. Then $2 \leq \operatorname{odd}\left(G-\left\{v_{1}, v_{3}\right\}\right)<$ $\left|\left\{v_{1}, v_{3}\right\}\right|=2$, a contradiction. Hence $G$ is 2-edge connected.

Claim 3. $\delta(G) \geq 3$.
Proof. By Claim 2, $\delta(G) \geq 2$. Assume that $\delta(G)=2$ and $\operatorname{deg}_{G}(v)=2$ for some vertex $v$. Let $x$ and $y$ be the two vertices adjacent to $v$ in $G$. Since $|G|$ is even, $G-\{x, y\}$ has at least two odd components including $\{v\}$, which implies $2 \leq \operatorname{odd}(G-\{x, y\})<|\{x, y\}|=2$, a contradiction. Hence $\delta(G) \geq 3$.

Consequently, by Lemma $10, G$ has an even factor.
Proof of Theorem 4 under the condition (ii). Assume that a graph $G$ satisfies the condition (ii). Then $|G|$ is odd and $|G| \geq 3$.

Claim 1. $G$ is connected.
Proof. Assume that $G$ is not connected. Let $G=H_{1} \cup H_{2} \cup \cdots \cup H_{m}$ be the decomposition of $G$ into its components, where $m \geq 2$. If a component $H_{a}$ has even order, then take a vertex $v_{1} \in V\left(H_{a}\right)$. Then $1 \leq \operatorname{odd}\left(G-v_{1}\right)<(2 / 3)\left|\left\{v_{1}\right\}\right|<$ 1, a contradiction. Hence every component $H_{i}$ has odd order. If a component $H_{b}$ has order at least 3 , we consider two vertices $v_{2}, v_{3} \in V\left(H_{b}\right)$. Then $2 \leq m \leq$ $\operatorname{odd}\left(G-\left\{v_{2}, v_{3}\right\}\right)<(2 / 3)\left|\left\{v_{2}, v_{3}\right\}\right|<2$, a contradiction. Hence every component
$H_{i}$ has order 1, and $m=|G| \geq 3$. Then we have $2 \leq m-1=\operatorname{odd}\left(G-V\left(H_{1}\right)\right)<$ $(2 / 3)\left|V\left(H_{1}\right)\right|<1$, a contradiction. Therefore $G$ is connected.

Claim 2. $G$ is 2-edge connected.
Proof. Assume that $G$ is not 2-edge connected. Then there exists an edge $e=$ $x y \in E(G)$ such that $G-e$ consists of two components $D_{1}$ and $D_{2}$ with $x \in V\left(D_{1}\right)$ and $y \in V\left(D_{2}\right)$. Since $|G|$ is odd, we may assume that $\left|D_{1}\right|$ is odd and $\left|D_{2}\right|$ is even. Then $2 \leq \operatorname{odd}(G-\{y\})<(2 / 3)|\{y\}|<1$, a contradiction. Hence $G$ is 2-edge connected.

By Claim $2, \delta(G) \geq 2$. If $|G|=3$, then $G$ is a cycle of order 3 , which is an even factor. Thus we may assume that $|G| \geq 5$.
Claim 3. $G$ is 3 -connected, and so $\delta(G) \geq 3$.
Proof. Assume that $G-\{x, y\}$ is not connected for some two vertices $x$ and $y$. Then $1 \leq \operatorname{odd}(G-\{x, y\})<(2 / 3)|\{x, y\}|=4 / 3$. Thus $\operatorname{odd}(G-\{x, y\})=1$. Let $G-\{x, y\}=C_{1} \cup D_{1} \cup \cdots \cup D_{t}, t \geq 1$, where $C_{1}$ is an odd component and all $D_{i}$ are even components. Take a vertex $z \in V\left(D_{1}\right)$. Then $2 \leq \operatorname{odd}(G-\{x, y, z\})<$ $(2 / 3) \cdot 3=2$, a contradiction. Hence $G$ is 3-connected.

Consequently, by Lemma 10, $G$ has an even factor.

## 3. Proofs of Theorems 5 and 6

Recall that $\omega(G)$ denotes the number of components of a graph $G$. A graph $G$ is said to be $k$-tough if $\omega(G-S) \leq|S| / k$ for all $S \subset V(G)$ with $\omega(G-S) \geq 2$. In order to prove Theorems 5 and 6 , we need the following two theorems.

Theorem 11 (Enomoto, Jackson, Katerinis, Saito [5]). Let $k \geq 2$ be an integer and $G$ be a graph. If $G$ is $k$-tough, $|G| \geq k+1$ and $k|G|$ is even, then $G$ has a $k$-regular factor.

Theorem 12 (Lu and Kano [9]). Let $G$ be a connected graph. If

$$
\begin{equation*}
\omega(G-S) \leq|S| \quad \text { for all } \quad \emptyset \neq S \subset V(G) \tag{7}
\end{equation*}
$$

then for every vertex-labeling $h: V(G) \rightarrow\{$ red, blue $\}$ with $\#\{v \in V(G): f(v)=$ red $\}$ even, $G$ has a spanning subgraph $F$ such that

$$
\operatorname{deg}_{F}(x)=1 \quad \text { if } \quad h(x)=\text { red, } \quad \text { and } \quad \operatorname{deg}_{F}(x) \in\{0,2\} \quad \text { otherwise } .
$$

We simultaneously prove Theorems 5 and 6 since they can be proved in the same way.

Proofs of Theorems 5 and 6. Assume that a graph $G$ satisfies the conditions of Theorems 5 or 6 . We start with the following claim.

Claim 1. $G$ is $(k-1)$-tough for all $k \geq 2$.
Proof. Assume that $G$ is not ( $k-1$ )-tough. Then there exists a subset $X \subset V(G)$ such that $\omega(G-X)>|X| /(k-1)$ and $\omega(G-X) \geq 2$. Let $G-X=C_{1} \cup \cdots \cup C_{s} \cup$ $D_{1} \cup \cdots \cup D_{t}$, where $C_{1}, \ldots, C_{s}$ are the odd components of $G-X$ and $D_{1}, \ldots, D_{t}$ are the even components of $G-X$. Thus we have $s+t=\omega(G-X)>|X| /(k-1)$, and so

$$
\begin{equation*}
|X|<(k-1)(s+t) . \tag{8}
\end{equation*}
$$

Consider a vertex $x_{i} \in V\left(D_{i}\right)$ for each $1 \leq i \leq t$. Then $\operatorname{odd}\left(D_{i}-x_{i}\right) \geq 1$ since $D_{i}$ is of even order. Hence, by (4) or (5), we have

$$
s+t \leq o d d\left(G-X \cup\left\{x_{1}, \ldots, x_{t}\right\}\right) \leq \frac{|X|+t}{k}
$$

Thus we obtain

$$
\begin{equation*}
k s+(k-1) t \leq|X| . \tag{9}
\end{equation*}
$$

By (8) and (9), we have

$$
k s+(k-1) t<(k-1)(s+t) .
$$

This implies that $s<0$, which is a contradiction. Therefore, Claim 1 holds.
If $k \geq 3$, then $G$ has a $(k-1)$-regular factor by Claim 1 and Theorem 11 . Hence Theorem 5 holds. If $k=2$, then (7) holds by Claim 1. Therefore Theorem 6 follows from Theorem 12.
