#### Abstract

A regular graph is co-edge regular if there exists a constant $\mu$ such that any two distinct and non-adjacent vertices have exactly $\mu$ common neighbors. In this paper, we show that for integers $s \geq 2$ and $n$ large enough, any co-edge-regular graph which is cospectral with the $s$-clique extension of the triangular graph $T(n)$ is exactly the $s$-clique extension of the triangular graph $T(n)$.

Keywords: co-edge-regular graph, $s$-clique extension, triangular graph.
2010 Mathematics Subject Classification: 05C50, 05C75, 05C62.

[^0]
## 1. Introduction

All graphs in this paper are simple and undirected. For definitions related to distance-regular graphs, see $[1,11]$. Before we state the main result, we give more definitions.

Let $G$ be a simple connected graph on vertex set $V(G)$, edge set $E(G)$ and adjacency matrix $A$. The eigenvalues of $G$ are the eigenvalues of $A$. Let $\lambda_{0}, \lambda_{1}, \ldots, \lambda_{t}$ be the distinct eigenvalues of $G$ and $m_{i}$ be the multiplicity of $\lambda_{i}(i=0,1, \ldots, t)$. Then the multiset $\left\{\lambda_{0}^{m_{0}}, \lambda_{1}^{m_{1}}, \ldots, \lambda_{t}^{m_{t}}\right\}$ is called the spectrum of $G$. Two graphs are called cospectral if they have the same spectrum. Note that a graph $H$ cospectral with a $k$-regular graph $G$ is also $k$-regular.

Recall that a regular graph is called co-edge-regular, if there exists a constant $\mu$ such that any two distinct and non-adjacent vertices have exactly $\mu$ common neighbors. Our main result in this paper is as follows.

Theorem 1. Let $\Gamma$ be a co-edge-regular graph with spectrum

$$
\left\{(2 s n-3 s-1)^{1},(s n-3 s-1)^{n-1},(-s-1)^{\frac{n^{2}-3 n}{2}},(-1)^{\frac{(s-1) n(n-1)}{2}}\right\}
$$

where $s \geq 2$ and $n \geq 1$ are integers. If $n \geq 48 s$, then $\Gamma$ is the s-clique extension of the triangular graph $T(n)$.

This paper is a follow-up paper of Hayat, Koolen and Riaz [4]. They showed a similar result for the square grid graphs. In that paper, they gave the following conjecture.

Conjecture 2 [4]. Let $\Gamma$ be a connected co-edge-regular graph with four distinct eigenvalues. Let $t \geq 2$ be an integer and $|V(\Gamma)|=n(\Gamma)$. Then there exists a constant $n_{t}$ such that, if $\theta_{\min }(\Gamma) \geq-t$ and $n(\Gamma) \geq n_{t}$ both hold, then $\Gamma$ is the $s$-clique extension of a strongly regular graph for some $2 \leq s \leq t-1$.

This conjecture is wrong as the $p \times q$-grids $(p>q \geq 2)$ show. So we would like to modify this conjecture as follows.

Conjecture 3. Let $\Gamma$ be a connected co-edge-regular graph with parameters ( $n$, $k, \mu)$ having four distinct eigenvalues. Let $t \geq 2$ be an integer. Then there exists a constant $n_{t}$ such that, if $\theta_{\min }(\Gamma) \geq-t, n \geq n_{t}$ and $k<n-2-\frac{(t-1)^{2}}{4}$, then either $\Gamma$ is the s-clique extension of a strongly regular graph for $2 \leq s \leq t-1$ or $\Gamma$ is a $p \times q$-grid with $p>q \geq 2$.

The reason for the valency condition is, that in [12], it was shown that for $\lambda \geq 2$, there exist constants $C(\lambda)$ such that a connected $k$-regular co-edge-regular graph with order $v$ and smallest eigenvalue at least $-\lambda$ satisfies one of the following conditions.
(i) $v-k-1 \leq \frac{(\lambda-1)^{2}}{4}+1$, or;
(ii) Every pair of distinct non-adjacent vertices has at most $C(\lambda)$ common neighbours.
Koolen et al. [8] improved this result by showing that one can take $C(\lambda)=$ $(\lambda-1) \lambda^{2}$ if $k$ is much larger than $\lambda$. This paper is part of the project to show the conjecture for $t=3$.

Another motivation comes from the lecture notes [9]. In these notes, Terwilliger shows that any local graph of a thin $Q$-polynomial distance-regular graph is co-edge-regular and has at most five distinct eigenvalues. So it is interesting to study co-edge-regular graphs with a few distinct eigenvalues.

We mainly follow the method of Hayat et al. [4]. The main difference is that we simplify the method of Hayat et al. when we show that every vertex lies on exactly two lines. This leads to a better bound for which we can show this. This will also improve the bound given in the result of Hayat et al.

## 2. Preliminaries

### 2.1. Definitions

For two distinct vertices $x$ and $y$, we write $x \sim y$ (respectively, $x \nsim y$ ) if they are adjacent (respectively, nonadjacent) to each other. For a vertex $x$ of $G$, we define $N_{G}(x)=\{y \in V(G) \mid y \sim x\}$, and $N_{G}(x)$ is called the neighborhood of $x$. The graph induced by $N_{G}(x)$ is called the local graph of $G$ with respect to $x$ and is denoted by $G(x)$. We denote the number of common neighbors between two distinct vertices $x$ and $y$ by $\lambda_{x, y}$ (respectively, $\mu_{x, y}$ ) if $x \sim y$ (respectively, $x \nsim y$ ).

A graph is called regular if every vertex has the same valency. A regular graph $G$ with $n$ vertices and valency $k$ is called co-edge-regular with parameters ( $n, k, \mu$ ) if any two nonadjacent vertices have exactly $\mu=\mu(G)$ common neighbors. In addition, if any two adjacent vertices have precisely $\lambda=\lambda(G)$ common neighbors, then $G$ is called strongly regular with parameters $(n, k, \lambda, \mu)$. A graph $G$ is called walk-regular if the number of closed walks of length $r$ from a given vertex $x$ is independent of the choice of $x$ for all $r$, that is to say, for any $x, A_{x x}^{r}$ is constant for all $r$, where $A$ is the adjacency matrix of $G$.

Let $X$ be a set of size $t$. The Johnson graph $J(t, d)(t \geq 2 d)$ is a graph with vertex set $\binom{X}{d}$, the set of $d$-subsets of $X$, where two $d$-subsets are adjacent whenever they have $d-1$ elements in common. $J(t, 2)$ is the triangular graph $T(t)$. Recall that a clique (or a complete graph) is a graph in which every pair of vertices is adjacent. A coclique is a graph that any two distinct vertices are nonadjacent. A $t$-clique is a clique with $t$-vertices and is denoted by $K_{t}$. The line graph of $K_{t}$ is also the triangular graph $T(t)$ which is strongly regular with
parameters $\left.\binom{t}{2}, 2 t-4, t-2,4\right)$ and spectrum $\left\{(2 t-4)^{1},(t-4)^{t-1},(-2)^{\frac{t^{2}-3 t}{2}}\right\}$.
The Kronecker product $M_{1} \otimes M_{2}$ of two matrices $M_{1}$ and $M_{2}$ is obtained by replacing the $i j$-entry of $M_{1}$ by $\left(M_{1}\right)_{i j} M_{2}$ for all $i$ and $j$. Note that if $\tau$ and $\eta$ are eigenvalues of $M_{1}$ and $M_{2}$, respectively, then $\tau \eta$ is an eigenvalue of $M_{1} \otimes M_{2}$.

### 2.2. Interlacing

Lemma 4 ([6], Interlacing). Let $N$ be a real symmetric $n \times n$ matrix with eigenvalues $\theta_{1} \geq \cdots \geq \theta_{n}$ and $R$ be a real $n \times m(m<n)$ matrix with $R^{T} R=I$. Set $M=R^{T} N R$ with eigenvalues $\mu_{1} \geq \cdots \geq \mu_{m}$. Then
(i) the eigenvalues of $M$ interlace those of $N$, i.e.,

$$
\theta_{i} \geq \mu_{i} \geq \theta_{n-m+i}, \quad i=1,2, \ldots, m
$$

(ii) if the interlacing is tight, that is, there exists an integer $j \in\{1,2, \ldots, m\}$ such that $\theta_{i}=\mu_{i}$ for $1 \leq i \leq j$ and $\theta_{n-m+i}=\mu_{i}$ for $j+1 \leq i \leq m$, then $R M=N R$.
In the case that $R$ is permutation-similar to $\left(\begin{array}{cc}I & O \\ O & O\end{array}\right)$, then $M$ is just a principal submatrix of $N$.

Let $\pi=\left\{V_{1}, \ldots, V_{m}\right\}$ be the partition of the index set of the columns of $N$ and let $N$ be partitioned according to $\pi$ as

$$
\left(\begin{array}{ccc}
N_{1,1} & \ldots & N_{1, m} \\
\vdots & \ddots & \vdots \\
N_{m, 1} & \ldots & N_{m, m}
\end{array}\right)
$$

where $N_{i, j}$ denotes the block matrix of $N$ formed by rows in $V_{i}$ and columns in $V_{j}$. The characteristic matrix $P$ is the $n \times m$ matrix whose $j$ th column is the characteristic vector of $V_{j}(j=1, \ldots, m)$. The quotient matrix of $N$ with respect to $\pi$ is the $m \times m$ matrix $Q$ whose entries are the average row sum of the blocks $N_{i j}$ of $N$, i.e.,

$$
Q_{i, j}=\frac{1}{V_{i}}\left(P^{T} N P\right)_{i, j}
$$

The partition $\pi$ is called equitable if each block $N_{i, j}$ of $N$ has constant row (and column) sum, i.e., $P Q=N P$. The following lemma can be shown by using Lemma 4.

Lemma 5 [5]. Let $N$ be a real symmetric matrix with $\pi$ as a partition of the index set of its columns. Suppose $Q$ is the quotient matrix of $N$ with respect to $\pi$, then the following hold.
(i) The eigenvalue of $Q$ interlace the eigenvalues of $N$.
(ii) If the interlacing is tight (as defined in Lemma 4(ii)), then the partition $\pi$ is equitable.

By an equitable partition of a graph, we always mean an equitable partition of its adjacency matrix $A$.

### 2.3. Clique extensions of $\boldsymbol{T}(\boldsymbol{n})$

In this subsection, we define $s$-clique extensions of graphs and we will give some specific results for the $s$-clique extension of triangular graphs.

Recall an $s$-clique is a clique with $s$ vertices, where $s$ is a positive integer. The s-clique extension of a graph $G$ with $|V(G)|$ vertices is the graph $\widetilde{G}$ obtained from $G$ by replacing each vertex $x \in V(G)$ by a clique $\widetilde{X}$ with $s$ vertices, satisfying $\widetilde{x} \sim \widetilde{y}$ in $\widetilde{G}$ if and only if $x \sim y$ in $G$, where $\widetilde{x} \in \widetilde{X}, \widetilde{y} \in \widetilde{Y}$. If $\widetilde{G}$ is an $s$-clique extension of $G$, then the adjacency matrix of $\widetilde{G}$ is $\left(A+I_{|V(G)|}\right) \otimes J_{s}-I_{s|V(G)|}$, where $J_{s}$ is the all-ones matrix of size $s$ and $I_{|V(G)|}$ is the identity matrix of size $|V(G)|$. In particular, if $G$ has $t+1$ distinct eigenvalues and its spectrum is

$$
\begin{equation*}
\theta_{0}^{m_{0}}, \theta_{1}^{m_{1}}, \ldots, \theta_{t}^{m_{t}} \tag{2.1}
\end{equation*}
$$

then the spectrum of $\widetilde{G}$ is

$$
\begin{align*}
& \left\{\left(s\left(\theta_{0}+1\right)-1\right)^{m_{0}},\left(s\left(\theta_{1}+1\right)-1\right)^{m_{1}}, \ldots\right.  \tag{2.2}\\
& \left.\left(s\left(\theta_{t}+1\right)-1\right)^{m_{t}},(-1)^{(s-1)\left(m_{0}+m_{1}+\cdots+m_{t}\right)}\right\} .
\end{align*}
$$

Note that if the adjacency matrix $A$ of a connected regular graph $G$ with $|V(G)|$ vertices and valency $k$ has four distinct eigenvalues $\left\{\theta_{0}=k, \theta_{1}, \theta_{2}, \theta_{3}\right\}$, then $A$ satisfies the following equation (see [7]):

$$
\begin{equation*}
A^{3}-\left(\sum_{i=1}^{3} \theta_{i}\right) A^{2}+\left(\sum_{1 \leq i<j \leq 3} \theta_{i} \theta_{j}\right) A-\theta_{1} \theta_{2} \theta_{3} I=\frac{\prod_{i=1}^{3}\left(k-\theta_{i}\right)}{|V(G)|} J . \tag{2.3}
\end{equation*}
$$

This implies that $G$ is walk-regular, see [10].
Now we assume $\Gamma$ is a cospectral graph with the $s$-clique extension of the triangular graph $T(n)$, where $s \geq 2$ and $n \geq 4$ are integers. Then by (2.1) and (2.2), the graph $\Gamma$ has spectrum

$$
\begin{align*}
& \left\{\theta_{0}^{m_{0}}, \theta_{1}^{m_{1}}, \theta_{2}^{m_{2}}, \theta_{3}^{m_{3}}\right\} \\
& =\left\{(s(2 n-3)-1)^{1},(s(n-3)-1)^{n-1},(-s-1)^{\frac{n^{2}-3 n}{2}},(-1)^{\left.(s-1)^{\frac{n(n-1)}{2}}\right\} .}\right. \tag{2.4}
\end{align*}
$$

Note that $\Gamma$ is regular with valency $k$, where $k=(s-1)+2(n-2) s=s(2 n-3)-1$. Using (2.3), we obtain

$$
\begin{aligned}
& A^{3}+(3+4 s-s n) A^{2}+\left((3-n) s^{2}+(8-2 n) s+3\right) A \\
& +\left(1-(n-4) s-(n-3) s^{2}\right) I=4 s^{2}(2 n-3) J .
\end{aligned}
$$

Therefore,

$$
A_{x y}^{3}= \begin{cases}2 s^{2} n^{2}-2 s^{2} n-6 s n-3 s^{2}+9 s+2, & \text { if } x=y  \tag{2.5}\\ 9 s^{2} n+2 s n-15 s^{2}-8 s-3-(3+4 s-s n) \lambda_{x y}, & \text { if } x \sim y \\ 8 s^{2} n-12 s^{2}-(3+4 s-s n) \mu_{x y}, & \text { if } x \nsim y\end{cases}
$$

The following result is known as the Hoffman bound.
Lemma 6 (Cf. [2], Theorem 3.5.2). Let $X$ be a $k$-regular graph with least eigenvalue $\tau$. Let $\alpha(X)$ be the size of maximum coclique in $X$. Then

$$
\alpha(X) \leq \frac{|X|(-\tau)}{k-\tau} .
$$

If equality holds, then each vertex not in a coclique of size $\alpha(X)$ has exactly $-\tau$ neighbours in it.

Applying Lemma 6 to the complement of $\Gamma$, we obtain the following lemma.
Lemma 7. For any clique $C$ of $\Gamma$ with order $c$, we have

$$
c \leq s(n-1) .
$$

If equality holds, then every vertex $x \in V(\Gamma) \backslash V(C)$ has exactly $2 s$ neighbors in $C$.

## 3. Lines in $\Gamma$

Recall that $\Gamma$ is a graph that is cospectral with the $s$-clique extension of the triangular graph $T(n)$, where $s \geq 2$ and $n \geq 1$ are integers. This implies that $\Gamma$ is walk-regular. Now we assume that $\Gamma$ is also co-edge-regular, i.e., there exist precisely $\mu=\mu(\Gamma)$ common neighbors between any two distinct nonadjacent vertices of $\Gamma$. Note that for $\Gamma$, we have $\mu=4 s$ from the spectrum of the $s$-clique extension of $T(n)$.

Fix a vertex, denoted by $\infty$ and let $\Gamma(\infty)$ be the local graph of $\Gamma$ at vertex $\infty$. Let $V(\Gamma(\infty))=\left\{x_{1}, x_{2}, \ldots, x_{k}\right\}$, where $k=s(2 n-3)-1$. Let $x_{i}$ have valency $d_{i}$ inside $\Gamma(\infty)$ for $i=1,2, \ldots, k$. Because $\Gamma$ is walk-regular, the number of closed walks through a fixed vertex $\infty$ of length 3 and 4 only depends on the spectrum.

This means that the number of edges in $\Gamma(\infty)$ is determined by the spectrum and as $\Gamma$ is co-edge-regular, we also see that the number of walks of length 2 in $\Gamma(\infty)$ is determined by the spectrum of $\Gamma$. This implies these numbers are the same as in a local graph of the $s$-clique extension of $T(n)$.

Let $\Delta$ be the $s$-clique extension of $T(n)$. Fix a vertex $u$ of $\Delta$. Then there are $s-1$ vertices with valency $(s-2)+2 s(n-2)$ and $2 s(n-2)$ vertices with valency $s(n-2)+2(s-1)$ in the local graph of $T(n)$ with respect to a fixed vertex. Using (2.5), this implies that the sum of valencies and the sum of square of valencies of vertices in $\Gamma(\infty)$ are constant, and are given by the following equations.

$$
\begin{gather*}
\sum_{i=1}^{k} d_{i}=2 \varepsilon=2 s^{2} n^{2}-2 s^{2} n-6 s n-3 s^{2}+9 s+2,  \tag{3.1}\\
\sum_{i=1}^{k}\left(d_{i}\right)^{2}=2 s n\left(s^{2} n^{2}-6 s n-6 s^{2}+10 s+8\right)+9 s^{3}+3 s^{2}-24 s-4, \tag{3.2}
\end{gather*}
$$

where $\varepsilon$ is the number of edges inside $\Gamma(\infty)$. By (3.1) and (3.2), we obtain

$$
\begin{equation*}
\sum_{i=1}^{k}\left(d_{i}-(s n-2)\right)^{2}=(s-1) s^{2}(n-3)^{2} \tag{3.3}
\end{equation*}
$$

It turns out that (3.3) is of crucial importance in proving our main result. Now we show the following lemma that will be used later.

Lemma 8. Fix a vertex $\infty$ of $\Gamma$ and let $\Gamma(\infty)$ be the local graph of $\Gamma$ at $\infty$. Define $E=\left\{y \sim \infty \left\lvert\, d_{y}>\frac{3}{4} s(n-1)\right.\right\}$ and let $e=|E|$. Let $F=\left\{y \sim \infty \left\lvert\, d_{y} \leq \frac{3}{4} s(n-1)\right.\right\}$ and $f=|F|$. If $n \geq 55$, then the following hold.
(1) $f \leq 16(s-1)$.
(2) The subgraph of $\Gamma$ induced on $E$ is not complete.
(3) The subgraph of $\Gamma$ induced on $E$ does not contain a coclique of order three.

Proof. Note that $f=k-e$. As $\frac{3}{4} s(n-1)+1 \leq \frac{3}{4}(s n-2)$, by (3.3), we obtain

$$
\begin{align*}
(s-1) s^{2}(n-3)^{2}=\sum_{y \sim \infty}\left(d_{y}-(s n-2)\right)^{2} & \geq \sum_{y \in F}\left(d_{y}-(s n-2)\right)^{2} \\
& \geq \sum_{y \in F}\left(\frac{1}{4}(s n-2)\right)^{2}  \tag{3.4}\\
& =\frac{1}{16} f(s n-2)^{2} \geq \frac{1}{16} f(s n-s)^{2} .
\end{align*}
$$

So

$$
f \leq 16(s-1),
$$

which implies $f<\frac{1}{2}(s n-2)$ if $n \geq 55$ (and $s \geq 2$ ). This means

$$
e=k-f>s n .
$$

By Lemma 7, we obtain that $e$ is greater than the order of a maximum size clique and hence the subgraph induced on $E$ is not complete.

Now we show that $E$ does not contain a coclique of order three. Suppose $X \subset E$ is a coclique in $\Gamma(\infty)$ with vertices $\left\{x_{1}, x_{2}, x_{3}\right\}$. Define $A_{i}(i=1,2,3)$ such that

$$
A_{i}=\left\{y \sim \infty \mid y \sim x_{i}, y \nsim x_{j} \text { for all } x_{j} \in X, j \neq i\right\} \cup\left\{x_{i}\right\} .
$$

Since $\Gamma$ is co-edge-regular, the vertices $x_{i}$ and $x_{j}(i \neq j)$ have at most $4 s-1$ common neighbours. By the inclusion-exclusion principle, we have

$$
\frac{3 \times\left(\frac{3}{4} s(n-1)+1\right)-k}{3} \leq 4 s-1
$$

This gives $n<54$. This shows the lemma.
A maximal clique of $\Gamma$ is called a line if it contains more than $\frac{3}{4} s(n-1)$ vertices. We show the existence of lines of $\Gamma$ in the following.
Proposition 9. If $n \geq 48 s \geq 96$, then for every vertex $\infty$, there are exactly two lines through $\infty$, say $C_{1}$ and $C_{2}$. Denote $m=\left|V\left(C_{1}\right) \cap V\left(C_{2}\right) \backslash\{\infty\}\right|$ and $\ell=k+1-\left|V\left(C_{1}\right) \cup V\left(C_{2}\right)\right|$. Then $m \leq 4 s-1$ and $\ell \leq 16(s-1)$.
Proof. Fix a vertex $\infty$ of $\Gamma$, let $E=\left\{y \sim \infty \left\lvert\, d_{y}>\frac{3}{4} s(n-1)\right.\right\}$. By Lemma 8, a maximum coclique in $E$ has order two as $n \geq 48 s \geq 55$. Let $x_{1}, x_{2}$ be distinct nonadjacent vertices in $E$ and let $y \in E$. Then $y$ has at least one neighbour in $\left\{x_{1}, x_{2}\right\}$.

Let $A_{i}=\left\{y \in E \mid y \sim x_{i}, y \nsim x_{j}\right.$ for $\left.j=1,2, j \neq i\right\}$ for $i=1,2$. Then the subgraph induced on $A_{i}$ is complete for $i=1,2$. Let $C_{i}$ be a maximal clique containing the vertex set $\{\infty\} \cup A_{i}$ for $i=1,2$. Note that $C_{1} \neq C_{2}$ as $x_{1} \nsim x_{2}$. Let $M=V\left(C_{1}\right) \cap V\left(C_{2}\right) \backslash\{\infty\}$ and $L=V(\Gamma(\infty)) \backslash\left(V\left(C_{1}\right) \cup V\left(C_{2}\right)\right)$. Let $m=|M|$ and $\ell=|L|$. By the co-edge-regularity of $\Gamma$, we have $m \leq 4 s-1$. Let $F=\left\{y \sim \infty \left\lvert\, d_{y} \leq \frac{3}{4} s(n-1)\right.\right\}$ and $f=|F|$. We have, by Lemma 8 , that $f \leq 16(s-1)$.

Suppose $x \in E \backslash\left(V\left(C_{1}\right) \cup V\left(C_{2}\right)\right)$. Then $x$ has at least $\left(\frac{3}{4} s(n-1)-(4 s-\right.$ 2) $-16(s-1)) / 2$ neighbours in at least one of $C_{1}$ and $C_{2}$. If $n \geq 48 s \geq 96$, then this number is at least $4 s$, which is a contradiction. Hence $E \subseteq V\left(C_{1}\right) \cup V\left(C_{2}\right)$. So, $L \subseteq F$ and hence $\ell \leq f \leq 16(s-1)$ by Lemma 8. This shows that $\left|V\left(C_{1}\right)\right|+$ $\left|V\left(C_{2}\right)\right| \geq k-\ell \geq k-16(s-1)$. Assume $\left|V\left(C_{1}\right)\right| \geq\left|V\left(C_{2}\right)\right|$, then we see that

$$
\left|V\left(C_{2}\right)\right| \geq k-16(s-1)-s(n-1)>\frac{3}{4} s(n-1),
$$

as $n \geq 48 s \geq 96$. This gives that there are exactly two lines through $\infty$.

Now we prove the following property for lines through a vertex.
Lemma 10. Fix a vertex $\infty$ of $\Gamma$ and let $C_{1}$ and $C_{2}$ be the two lines through $\infty$ with respective orders $c_{1}$ and $c_{2}$. Let $L=V(\Gamma(\infty)) \backslash\left(V\left(C_{1}\right) \cup V\left(C_{2}\right)\right)$ and $M=V\left(C_{1}\right) \cap V\left(C_{2}\right) \backslash\{\infty\}$, and $\ell=|L|, m=|M| \geq 0$. If $n \geq 48 s \geq 96$, then $\ell+m=s-1$ and

$$
s(n-3)+1 \leq c_{i} \leq s(n-1)
$$

for $i=1,2$.
Proof. Let $Q=V\left(C_{1}\right) \Delta V\left(C_{2}\right)$, where $\Delta$ means "symmetric difference". Then, by Lemma $7,|Q| \leq\left|V\left(C_{1}\right)\right|+\left|V\left(C_{2}\right)\right| \leq 2 s(n-1)$.

Note that $Q$ is the complement of $L \cup M$ inside $V(\Gamma(\infty))$.
For $y \in M$, we have

$$
\begin{equation*}
2 s n-19 s \leq k-1-\ell \leq d_{y} \leq k-1=2 s n-3 s-2, \tag{3.5}
\end{equation*}
$$

by Proposition 9 .
Now let $y \in L$. Then $y$ has at least $4 s-1$ neighbors in each of $C_{1}$ and $C_{2}$. Hence, by Proposition 9, we obtain

$$
\begin{equation*}
d_{y} \leq 2 \times(4 s-1)+\ell-1 \leq 2(4 s-1)+16(s-1)-1 \leq 24 s . \tag{3.6}
\end{equation*}
$$

By (3.3), we obtain

$$
\begin{align*}
(s-1) s^{2}(n-3)^{2} & =\sum_{y \sim \infty}\left(d_{y}-(s n-2)\right)^{2} \\
& \geq \sum_{y \in L}\left(d_{y}-(s n-2)\right)^{2}+\sum_{y \in M}\left(d_{y}-(s n-2)\right)^{2}  \tag{3.7}\\
& \geq \ell((s n-s)-24 s)^{2}+m((2 s n-19 s)-s n)^{2} \\
& =\ell s^{2}(n-25)^{2}+m s^{2}(n-19)^{2} \geq(\ell+m) s^{2}(n-25)^{2} .
\end{align*}
$$

So

$$
\ell+m \leq \frac{(s-1)(n-3)^{2}}{(n-25)^{2}}<s
$$

if $n \geq 48 s$. Hence

$$
\begin{equation*}
\ell+m \leq s-1 \tag{3.8}
\end{equation*}
$$

This gives for $y \in L \cup M$, using (3.5), (3.6) and $l \leq s-1$, that

$$
d_{y}-(s n-2) \leq k-1-(s n-2)=s n-3 s .
$$

Note that by (3.8),

$$
\begin{align*}
s(n-1) & \geq\left|V\left(C_{j}\right)\right| \geq 1+k-s(n-1)-l \\
& \geq 2 s n-3 s-s(n-1)-(s-1)=s(n-3)+1 \tag{3.9}
\end{align*}
$$

for $j=1,2$.
For $y \in V(\Gamma(\infty)) \backslash(L \cup M)$, we obtain

$$
s n-4 s \leq\left|V\left(C_{2}\right)\right|-m-2 \leq d_{y} \leq\left|V\left(C_{2}\right)\right|-1+4 s-1+\ell \leq s n+4 s-3
$$

Hence $\left|d_{y}-(s n-2)\right| \leq 4 s$.
Now (3.3) gives us

$$
\begin{align*}
(s-1) s^{2}(n-3)^{2} & =\sum_{y \sim \infty}\left(d_{y}-(s n-2)\right)^{2} \\
& \leq \sum_{y \in L \cup M}\left(d_{y}-(s n-2)\right)^{2}+\sum_{y \in Q}\left(d_{y}-(s n-2)\right)^{2}  \tag{3.10}\\
& \leq(\ell+m) s^{2} n^{2}+2 s(n-1)(4 s)^{2}
\end{align*}
$$

So

$$
\ell+m \geq \frac{(s-1)(n-3)^{2}-32 s(n-1)}{n^{2}}>s-2
$$

if $n \geq 48 s \geq 96$. This implies $\ell+m=s-1$. This shows the lemma.
We obtain the following lemma immediately.
Lemma 11. Fix a vertex $\infty$ of $\Gamma$ and let $C_{1}$ and $C_{2}$ be the two lines through $\infty$ with respective orders $c_{1}$ and $c_{2}$. Assume $m=\left|V\left(C_{1}\right) \cap V\left(C_{2}\right) \backslash\{\infty\}\right|$. If $n \geq 48 s$, then $c_{1}+c_{2}=2 s(n-2)+2(m+1)$.

Proof. Let $\ell=\left|V(\Gamma(\infty)) \backslash\left(V\left(C_{1}\right) \cup V\left(C_{2}\right)\right)\right|$. Then we have

$$
\left(c_{1}-m-1\right)+\left(c_{2}-m-1\right)+m+\ell=k=2 s n-3 s-1
$$

If $n \geq 48 s$, then we have $\ell+m=s-1$ by Lemma 10, hence $c_{1}+c_{2}=2 s(n-$ $2)+2(m+1)$.

In the next two sections, we will follow the method as used in Hayat et al. [4].

## 4. The Order of Lines

In this section, we will show the following lemma on the order of lines.

Lemma 12. Let $s \geq 2$ and $n \geq 1$ be integers. Let $\Gamma$ be a co-edge-regular graph that is cospectral with the s-clique extension of the triangular graph $T(n)$. Let $q_{i}$ be the number of lines with order $s(n-3)+i$ for $i=1, \ldots, 2 s$ and $\delta=\sum_{i=1}^{2 s} q_{i}$ be the number of lines in $\Gamma$. Assume $n \geq 48$ s. Then

$$
\begin{equation*}
\sum_{i=1}^{2 s}(s(n-3)+i) q_{i}=s n(n-1) \tag{4.1}
\end{equation*}
$$

holds, and the number $\delta$ satisfies

$$
\begin{equation*}
n \leq \delta \leq n+2 \tag{4.2}
\end{equation*}
$$

If $\delta=n$, then $q_{i}=0$ for all $i<2 s$, and $q_{2 s}=n$.
Proof. Assume $n \geq 48$ s. By Proposition 9, any vertex of $\Gamma$ lies on exactly two lines. Now consider the set

$$
W=\{(x, C) \mid x \in V(C), \text { where } C \text { is a line }\} .
$$

Then, by double counting, the cardinality of the set $W$, we see (4.1). Moreover, we see that

$$
\delta=\sum_{i=1}^{2 s} q_{i}<\sum_{i=1}^{2 s} \frac{s(n-3)+i}{s(n-3)} q_{i}=n+2+\frac{6}{n-3} .
$$

Thus, if $n>10$, we obtain

$$
\delta \leq n+2
$$

On the other hand, we have

$$
\delta=\sum_{i=1}^{2 s} q_{i} \geq \sum_{i=1}^{2 s} \frac{s(n-3)+i}{s(n-1)} q_{i}=n
$$

This shows $\delta \geq n$, and $\delta=n$ implies that all lines have order $s(n-1)$, which means $q_{i} \neq 0$ if and only if $i=2 s$. This completes the proof.

## 5. The Neighborhood of a Line

In this section we will show the following proposition.
Proposition 13. Let $\Gamma$ be a co-edge-regular graph that is cospectral with the sclique extension of the triangular graph $T(n)$, where $s \geq 2, n \geq 1$ are integers. If $n \geq 48$ s, then $\Gamma$ contains exactly $n$ lines.

Proof. In Lemma 12, we have seen that the number $\delta$ of lines satisfies $n \leq \delta \leq$ $n+2$. Now we assume that $n+1 \leq \delta \leq n+2$, in order to obtain a contradiction. Let $q_{i}$ be the number of lines of order $s(n-3)+i$ in $\Gamma$, where $i=1, \ldots, 2 s$. Let $h$ be minimal such that $q_{h} \neq 0$. Then clearly, $1 \leq h \leq 2 s$. Fix a line $C$ with exactly $s(n-3)+h$ vertices. Let $q_{i}^{\prime}$ be the number of lines $C^{\prime}$ with $s(n-3)+i$ vertices that intersect $C$ in at least one vertex. So $q_{i} \geq q_{i}^{\prime}$. By Lemma 11, we obtain

$$
\begin{equation*}
\left|V(C) \cap V\left(C^{\prime}\right)\right|=\frac{h+i-2 s}{2} . \tag{5.1}
\end{equation*}
$$

By Proposition 9, every vertex lies on exactly two lines, and hence we obtain

$$
\begin{equation*}
\sum_{i=1}^{2 s} q_{i}\left(\frac{h+i-2 s}{2}\right) \geq \sum_{i=1}^{2 s} q_{i}^{\prime}\left(\frac{h+i-2 s}{2}\right)=s(n-3)+h . \tag{5.2}
\end{equation*}
$$

Now multiply (5.2) by 2 and subtract (4.1) from obtained equation, we find

$$
\begin{equation*}
\delta(h+s(1-n))=\sum_{i=1}^{2 s} q_{i}(h+s(1-n)) \geq s\left(-n^{2}+3 n-6\right)+2 h \tag{5.3}
\end{equation*}
$$

as $\delta=\sum_{i=1}^{2 s} q_{i}$. This gives

$$
h(\delta-2) \geq 2 s(n-3)+(\delta-n) s(n-1) .
$$

As $n+1 \leq \delta \leq n+2$, we see
(5.4) $h n \geq h(\delta-2) \geq 2 s(n-3)+(\delta-n) s(n-1) \geq 2 s(n-3)+s(n-1)=3 s n-7 s$.

Since $n \geq 48 s$, (5.4) implies that $h \geq 3 s$. This contradicts to $h \leq 2 s$. This completes the proof.

## 6. Proof of the Main Result

In this section we show our main result, Theorem 1.
Proof of Theorem 1. Assume $n \geq 48$ s. By Propositions 9 and 13 and Lemma 12 , we find that there are exactly $n$ lines, each of order $s(n-1)$, and every vertex $x$ in $\Gamma$ lies on exactly two lines. Moreover, by Lemma 11, the two lines through any vertex $x$ have exactly $s$ vertices in common, and every neighbor of $x$ lies in one of the two lines through $x$. Now consider the following equivalence relation $\mathcal{R}$ on the vertex set $V(\Gamma): x \mathcal{R} x^{\prime}$ if and only if $\{x\} \cup N_{\Gamma}(x)=\left\{x^{\prime}\right\} \cup N_{\Gamma}\left(x^{\prime}\right)$, where $x, x^{\prime} \in V(\Gamma)$.

Every equivalence class under $\mathcal{R}$ contains $s$ vertices and it is the intersection of two lines. Let us define the graph $\hat{\Gamma}$ whose vertices are the equivalent classes and two classes, say $S_{1}$ and $S_{2}$, are adjacent in $\hat{\Gamma}$ if and only if any vertex in $S_{1}$ is adjacent to any vertex in $S_{2}$. Then $\hat{\Gamma}$ is a regular graph with valency $2 n-4$, and $\Gamma$ is the $s$-clique extension of $\hat{\Gamma}$. Note that the spectrum of $\hat{\Gamma}$ is equal to

$$
\left\{(2 n-4)^{1},(n-4)^{n-1},(-2)^{\frac{n^{2}-3 n}{2}}\right\},
$$

by the relation of the spectra of $\Gamma$ and $\hat{\Gamma}$, see (2.1) and (2.2). Since $\hat{\Gamma}$ is a connected regular graph with valency $2 n-4$, and it has exactly three distinct eigenvalues, it follows that $\hat{\Gamma}$ is a strongly regular graph with parameters $\left(\binom{n}{2}, 2 n-4, n-2,4\right)$.

As proved in [3], the triangular graphs are determined by the spectrum except when $n=8$. Since we assume that $n$ is large enough, the graph $\hat{\Gamma}$ is the triangular graph $T(n)$. This completes the proof.
