Abstract

Let $G_{2n}, H_{2n}$ be two non-isomorphic connected cubic multigraphs of order $2n$ with parallel edges permitted but without loops. Let $t(G_{2n}), t(H_{2n})$ denote the number of spanning trees in $G_{2n}, H_{2n}$, respectively. We prove that for $n \geq 3$ there is the unique $G_{2n}$ such that $t(G_{2n}) < t(H_{2n})$ for any $H_{2n}$. Furthermore, we prove that such a graph has $t(G_{2n}) = 5^22^{n-3}$ spanning trees. Based on our results we give a conjecture for the unique $r$-regular connected graph $H_{2n}$ of order $2n$ and odd degree $r$ that minimizes the number of spanning trees.

Keywords: cubic multigraph, spanning tree, regular graph, enumeration.
